# Outline

*Three on-going applications of the dual-frequency GNSS measurements available in real-time from hundreds of IGS permanent receivers will be presented and supported with new learning tools and exercises.*

*The corresponding synergic objectives are in the fields of Precise Farming, Space Weather and Real-Time Global Ionospheric Maps.*

# On-going applications of RT-IGS datastreams @ UPC-IonSAT

A) **Space Weather**: RT detection and estimation of the solar EUV flux rate, during solar flares with SISTED and GSFLAI GNSS indices. Maps of ionospheric scintillation (ROTI) and Medium Scale Travelling Ionospheric Disturbances (MSTID) activity proxies are also produced (started under MONITOR ESA project –see oral presentation of Alberto García-Rigo in ionospheric subsession-).

B) **Precise farming**: Improvement of precise RT positioning with Wide Area RTK technique and open-source software user receivers for the agriculture improvement in South Europe, where ionospheric modelling challenges, sparse GNSS networks and less funding availability for farmers coincide (ongoing AUDITOR H2020 EC project).

C) **RT-GIMs**: opportunities for combined IGS product

# Layout:

Satellite Systems  
Agency

HORIZON 2020

## Exp. 170613: Overview

### Presentation content

- ✓ Brief experiment description
- ✓ Relative dual-frequency real-time GPS positioning with TOMION

## AUDITOR

### Scenario:

✓ In Europe (typically at the South):

- 1) The **permanent GNSS networks can be sparse** (up to hundreds of kilometers of distance).
- 2) The **ionospheric delays can be large**.
- 3) The economy is not going so well.

### Problem:

✓ Precise farming in South of Europe will, then, require:

- 1) Prompt decimeter-error level real-time GNSS positioning at more than 100 km from the nearest GNSS reference site  
=> **Wide Area RTK**
- 2) Precise real-time ionospheric modelling from the measurements of the GNSS permanent networks => **Dual-layer tomography + Iono. wave modelling** (TOMION).
- 3) Open source GNSS source receiver, combining flexibility for new GNSS algorithms and affordability.

## Exper. 170613: Goal & Characteristics

### Experiment:

- ✓ **Precise Farming activity**: GNSS receiver (TOPCON GP-DX1) logging data for **several hours while spraying with a tractor**, which data has been kindly provided by Dirk De Hoog, WUR.
- ✓ Place: Experimental farm in Wageningen, **The Netherlands**, with **reference receiver BORJ at 190 km** far.
- ✓ Time: Day 13 June 2017 (doy 164), 06:11:39 to 13:30:59 GPS time.

### Goal:

- ✓ To analyze such recent AUDITOR experiment “170613” performed in actual precise farming conditions, **emulating Wide Area RTK processing in real-time**.

# Wide Area RTK in a nutshell: The independent DD phase ambiguities of two physical carriers

**DDBw** (widelane from Melbourne-Wubbenna  
combination,  $L_w - P_n$ )

**DDBc** (from  
ionospheric-free  
combination  $L_c$  - precise  
geometric modelling)

**DDBi** (from ionospheric  
combination  $L_I$  - precise  
ionospheric modelling)

# Wide Area RTK in a nutshell: How to improve the DD phase ambiguity fixing

**Geometry- & Ionospheric- free way**  
(Melbourne-Wubbenna combination, Lw-Pn)

**Ionospheric- free way**  
(Ionospheric-free combination Lc - precise geometric modelling)

**Geometry- free way**  
(Ionospheric combination LI - precise ionospheric modelling)

# Wide Area RTK in a nutshell: Basic equations on DDamb

Once  $\nabla\Delta N_\delta$  is fixed, it is possible to fix the  $L_1$  and  $L_2$  double-differenced integer ambiguities  $N_1$  and  $N_2$  for the reference stations, using a sufficiently accurate determination of the double-differenced ambiguity  $\nabla\Delta B_c$  of the ionospheric free combination  $L_c = (f_1^2 L_1 - f_2^2 L_2)/(f_1^2 - f_2^2)$ . The following relationships illustrate these steps:

$$\begin{aligned}\nabla\Delta B_c &= 0.5[\lambda_\delta \nabla\Delta N_\delta + \lambda_n \nabla\Delta(N_1 + N_2)] \\ \nabla\Delta(N_1 + N_2) &= \text{NI}[(2\nabla\Delta B_c - \lambda_\delta \nabla\Delta N_\delta)/\lambda_n] \\ \nabla\Delta N_1 &= 0.5[\nabla\Delta N_\delta + \nabla\Delta(N_1 + N_2)] \\ \nabla\Delta N_2 &= \nabla\Delta N_1 - \nabla\Delta N_\delta\end{aligned}\tag{3}$$

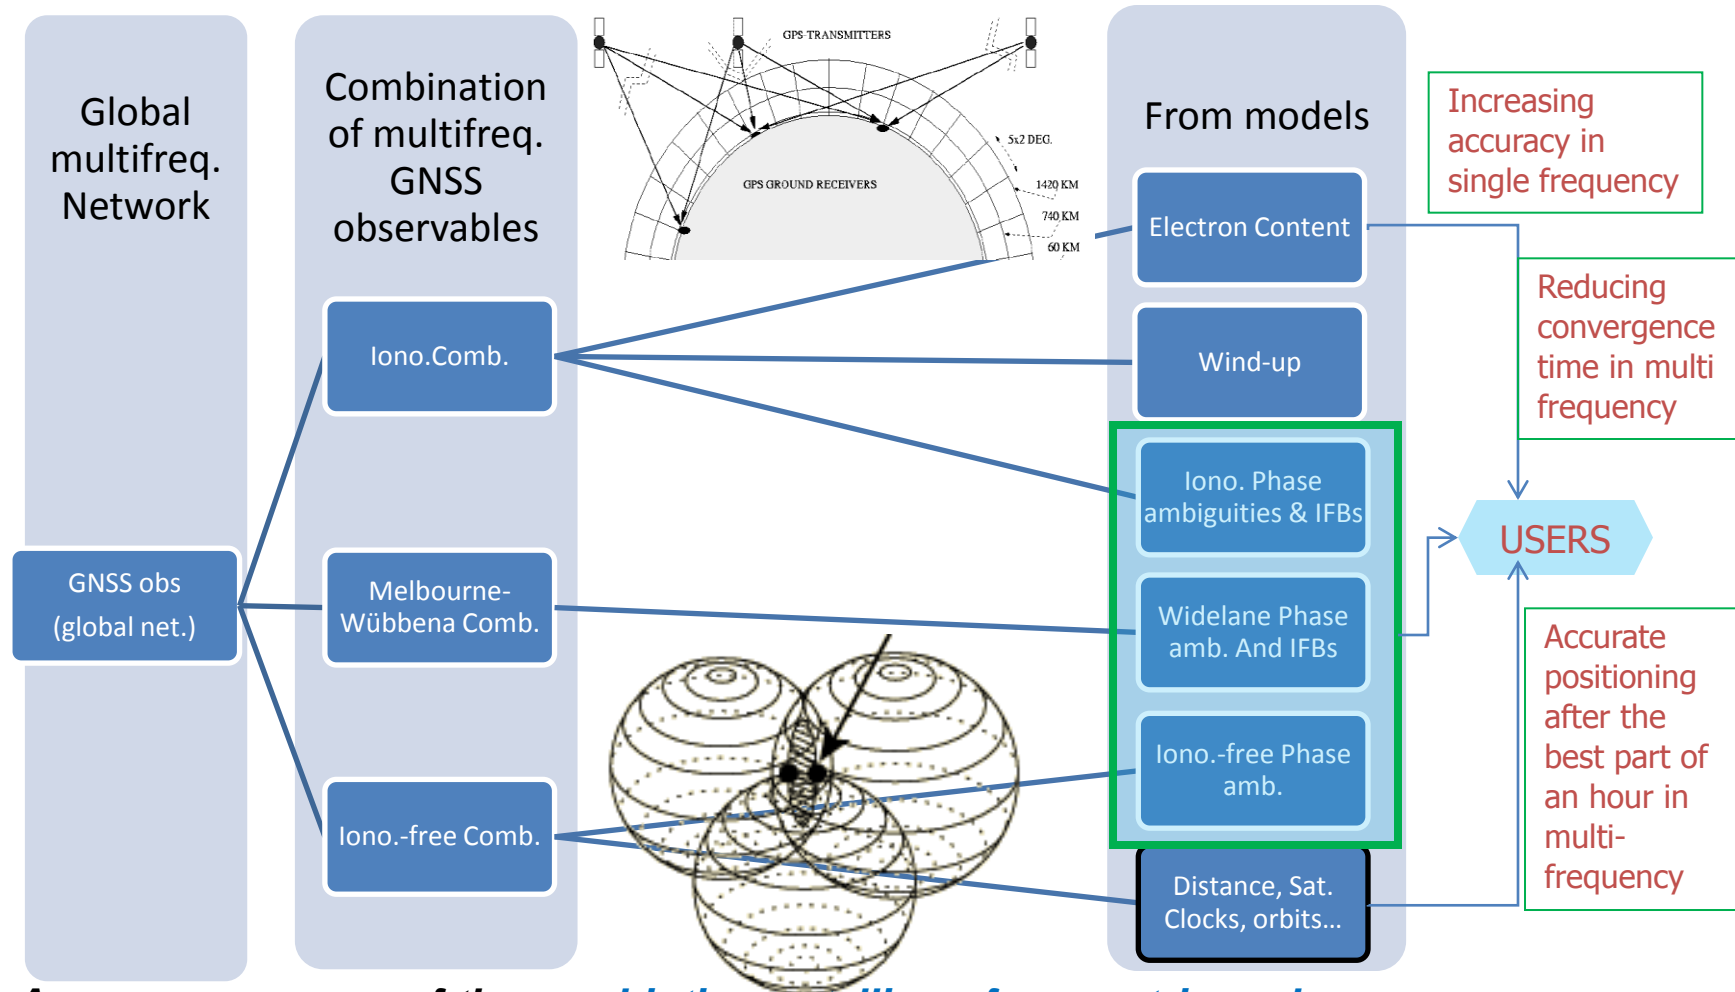

being  $\lambda_n = c/(f_1 + f_2) \simeq 10.7\text{cm}$  and NI the nearest integer. Hence, from  $\nabla\Delta N_1$  and  $\nabla\Delta N_2$ , the unambiguous double-differenced ionospheric slant total electron content, STEC, can be computed for the reference stations:

$$\alpha \nabla\Delta STEC = \nabla\Delta(L_1 - L_2) - (\lambda_1 \nabla\Delta N_1 - \lambda_2 \nabla\Delta N_2)\tag{4}$$

# T5.2 - GNSS network prefit module

## Hybrid ionospheric-geodetic approach

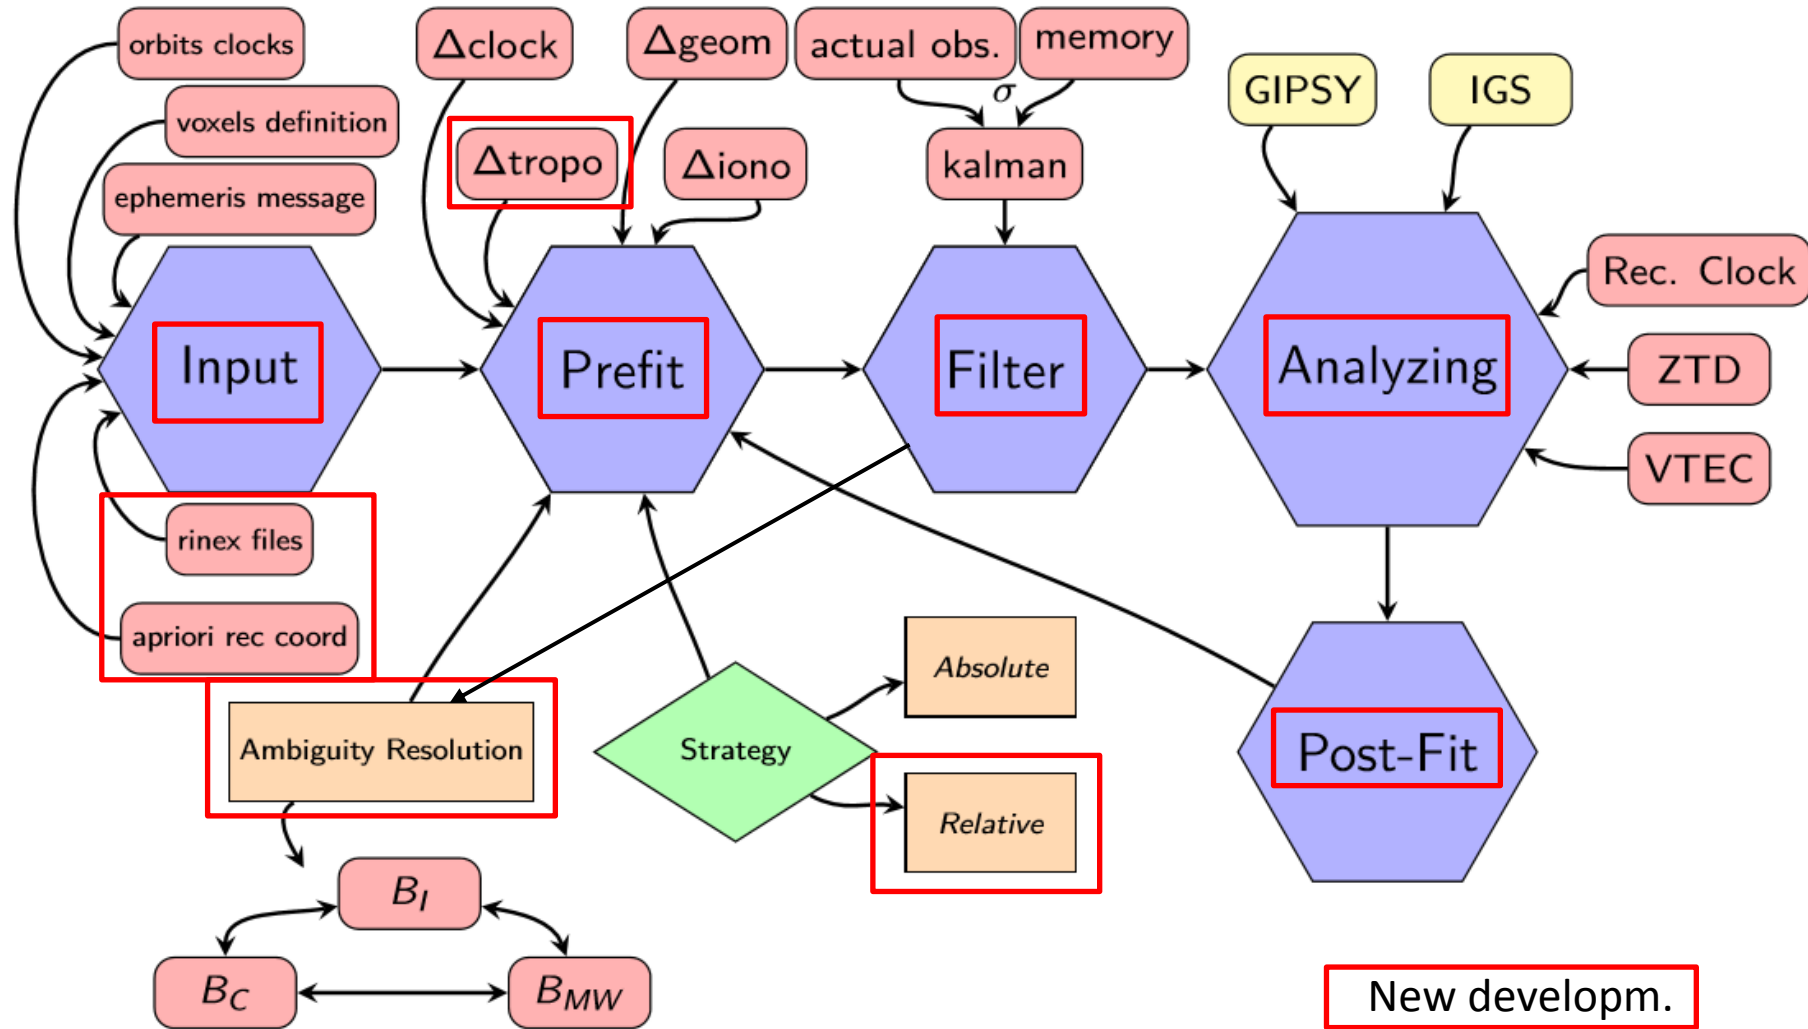

As a consequence of the *sybiotic modelling of geometric and ionospheric delay dependences of the GPS, Galileo, GLONASS & Beidou signals*: a **better positioning service is obtained** (cm-accuracy in real-time after short convergence time), and **better ionospheric sounding**

# T5.2 - GNSS network prefit module

## Hybrid ionospheric-geodetic approach

# Exp. 170613: Relative RT-mode dual-frequency positioning of Tractor (tpsd) vs Ref. Rec. (borj) with TOMION (1 of 4)

Rec. Id.	Distance to BORJ / km
IJMU	188
TPSD	190

- ✓ Consistency of the most part of positions over the paths compatible with 10cm-error level RT positioning.
- ✓ But a **cloud of apparently very noisy estimated positions appear**. Why? Cold start? Other reasons?

# Exp. 170613: Relative RT-mode dual-frequency positioning of Tractor (tpsd) vs Ref. Rec. (borj) with TOMION (2 of 4)

✓ The **big positioning errors** are NOT concentrated on the initial convergence phase of the tractor navigation (beginning of time-frame #1): **they appear when the tractor moves through one part of the path** (red arrow)

✓ Which can be the potential explanation?

# Exp. 170613: Relative RT-mode dual-frequency positioning of Tractor (tpsd) vs Ref. Rec. (borj) with TOMION (3 of 4)

- ✓The **potential reason of such very large positioning error** when moving during the same path (marked by the red arrow) is strongly suggested when the 3D representation is activated at google-earth: **THE CANOPY** (trees densely distributed in such part of the path).
- ✓The **trees**, affecting to this part of the path, are likely **blocking the signal of many GPS satellites generating cycle-slips and the corresponding re-initialization** of the carrier phase ambiguity estimation.
- ✓The **convergence phase of the positioning can be clearly seen** (within yellow ellipse), lasting for about ~25 seconds.

# Exp. 170613: Relative RT-mode dual-frequency positioning of Tractor (tpsd) vs Ref. Rec. (borj) with TOMION (4 of 4)

✓ The **association of the precise positioning outage with the canopy** and **not with the initial cold start of the tractor movement**, during the very first minutes (starting on 06:11:39) can be seen in the Way Points number labels (equivalent to time in seconds since tractor receiver starting): the erroneous positions happen within the range 1637-1658 and beyond (**red arrow**), while previous epochs are well located in previous path (**yellow arrow**).

## Exp. 170613: Relative RT-mode dual-frequency positioning of IJMU vs Ref. Rec. (borj) with licted satellite clocks & orbits, IGU)

Rec. Id.	Distance to BORJ / km
IJMU	188
TPSD	190

✓ Among the good fitting with the paths shown by google-earth, a more consistency indication of the decimeter error level navigation achieved by the relative dual-frequency carrier-phase based positioning on the tractor, has been obtained.

✓ We have processed the permanent receiver IJMU, also @ 1Hz, forming a similar baseline, in distance (188 km vs 190 km) and orientation (SW), than the Tractor (TPSD), comparing the IJMU RT-kinematic positioning, performed with the strategy than the one previously performed to TPSD, with the precise final PPP coordinates of IJMU, computed with postprocessing (rapid IGS) products, which can be taken as ground truth at centimeter error level: Errors up to +/- 20 cm, after the cold start (~4000 sec).

# Exp. 170613: Relative RT-mode dual-frequency positioning of IJMU vs Ref. Rec. (borj) with TOMION (rapid satellite clocks & orbits, IGR)

Rec. Id.	Distance to BORJ / km
IJMU	188
TPSD	190

- ✓ The result is almost the same when the predicted (“ultrarapid”) IGS products (IGU), available in real-time, are used (previous slide) and the postprocessing “rapid” IGS products (IGR) are used (this slide).
- ✓ This is the expected result when the relative RT approach is used (see modelling details in first slides).

# Exp. 170613: Relative RT-mode dual-frequency positioning of Tractor (tpsd) vs Ref. Rec. (borj) with TOMION: equivalent under IGU & IGR

Rec. Id.	Distance to BORJ / km
IJMU	188
TPSD	190

AUDITOR TPSD rover dual-freq. pos. relative to BORJ (+100 km far)

✓ As expected, the result is almost the same for the Tractor positioning (sub-mm discrepancies), when the predicted (“ultrarapid”) IGS products (IGU), available in real-time, are used (previous slide) and the postprocessing “rapid” IGS products (IGR) are used (this slide).

✓ The exceptions happen when a very large error happen (mostly on the canopy-affected part of the Tractor path studied before), when the precise real-time processing is interrupted.

# Exp. 170613, PPP static processing@15 min.: IGU (predicted clocks & orbits) vs IGR (rapid postprocessed clocks and orbits)

✓The influence of the degradation of (mainly) the predicted satellite clocks errors (IGU, first row) makes the PPP processing significantly worse than with postprocessed rapid (IGR) satellite clocks and orbits (second row), as expected.

# Exp. 170613: RT Relative dual-frequency positioning of IJMU vs. Ref. Rec. (borj) with TOMION (same time period than Tractor): No lono. + floating ambiguities

Rec. Id.	Distance to BORJ / km
IJMU	188
TPSD	190

✓ Convergence time of ~7000 sec (No lono. + floating ambiguities)

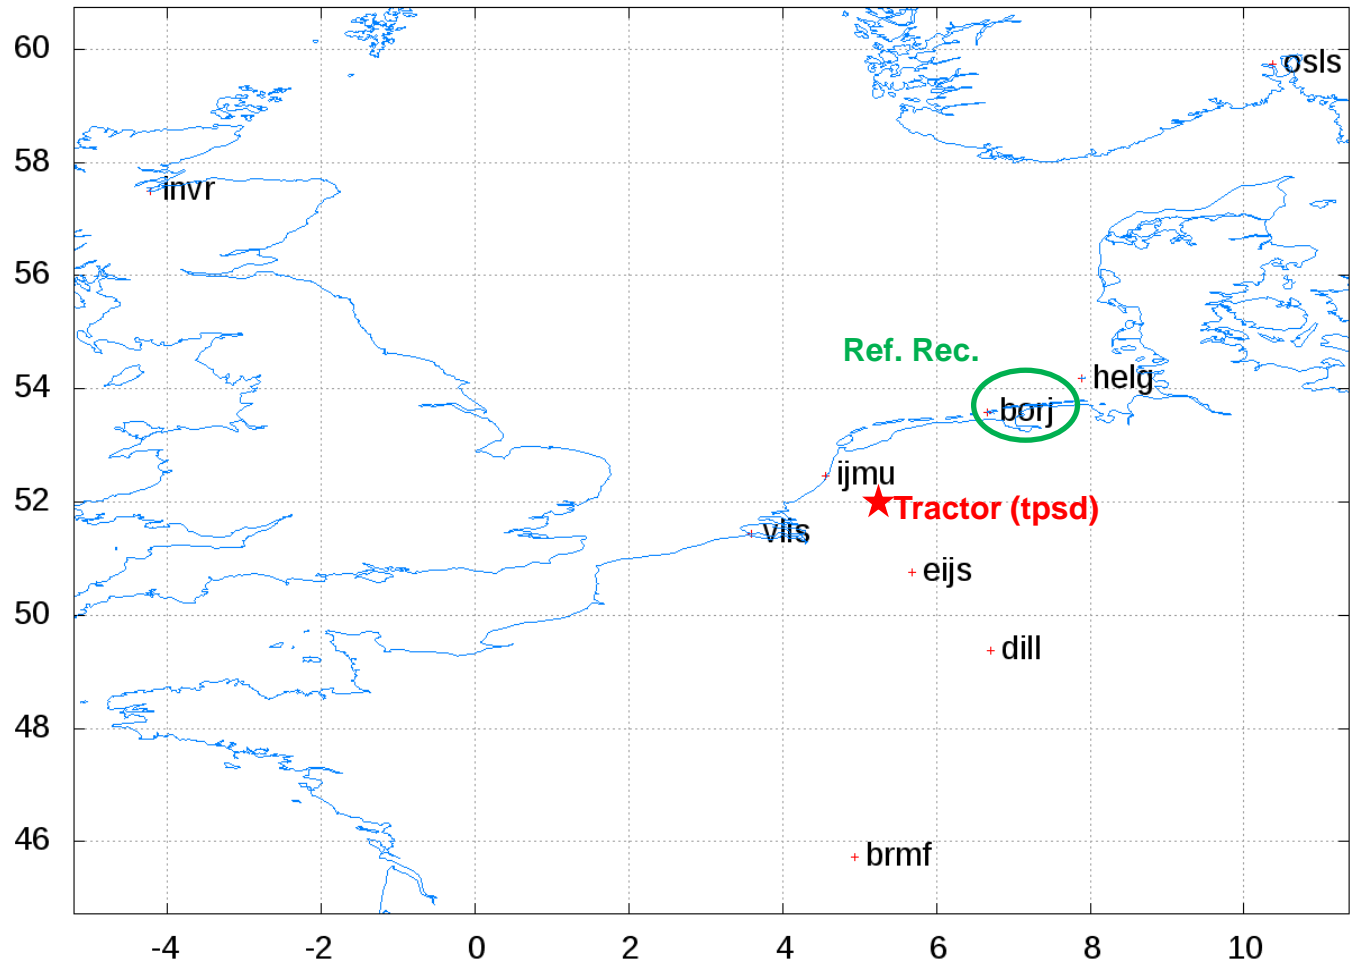

## Exp. 170613: Tractor & permanent network

AUDBASv1\_CPF\_TOMION

Rec. Id.	Distance to BORJ / km
HELG	104

OSLS	722
INVR	811
BRMF	882

Rec. Id.	Distance to BORJ / km
IJMU	188
TPSD	190

# Exp. 170613: RT Relative dual-frequency positioning of f. Rec. (borj) with TOMION (same time period Tractor): ambiguities constrained by RT iono.

✓Convergence time of ~2000 sec (ambiguities constrained by RT iono)

# Exp. 170613: RT Relative dual-frequency positioning of IJMU vs. Ref. Rec. (borj) with TOMION (same time period than Tractor): *hybrid amb. constrained & fixed by RT-iono*

Rec. Id.	Distance to BORJ / km
IJMU	188
TPSD	190

✓ Convergence time of ~4000 sec (hybrid amb. constrained & fixed by RT-iono, working CPF from 00h)

# Exp. 170613, RT-iono performance (PRN12) during full cold-start (compared with calibrated STEC in postprocess)

# Exp. 170613, Zenith Tropospheric Delay : **RT** relative processing @ 30sec vs postpr. (IGR) PPP processing@15 min.

✓ Another test of consistency of the same RT relative dual-frequency GPS processing is looking at the associated ZTD @ 30 sec., comparing them with the results with post-processed (IGR) PPP @ 15 min.

✓ The results are mostly in agreement under 1 cm level, with some deviations up to 3 cm for two given periods and for two stations.

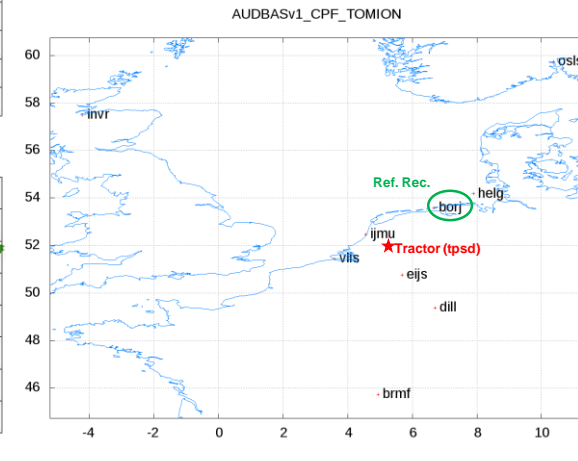

# Exp. 170613, Zenith Tropospheric Delay : **RT** relative processing @ 30sec vs postpr. (IGR) PPP processing@15 min. vs first results of relative processing fixing DD ambiguities from filter

✓The first results of the relative precise positioning after ambiguity fixing are very similar to the floated-ambiguities ones (at cm-level), excepting for the period [75000,80000] sec (likely due to a wrong ambiguity fixing).

## Conclusions

- ✓ The GPS data gathered from a tractor working 6 hours in a Netherlands farm, has been processed with the in-house UPC-IonSAT software, RT-TOMION.
- ✓ The analysis has been done emulating RT from dual-frequency carrier phase and pseudorange measurements, in relative processing approach, taking the reference station (BORJ) at around 190 km NE.
- ✓ The results show characteristics compatible with decimeter-error level RT-positioning (from fitting with exiting paths, equivalent analysis of IJMU, and ZTD results), excepting for an small sector under canopy.
- ✓ The satellite-clocks-proof in the quality of the relative processing, vs. undifference (PPP) one, has been exemplified as well during this experiment.
- ✓ The precise analysis of this farming exp. reinforces the need of looking for mitigation strategies of GNSS precise positioning under canopy (such as the one of Soloviev & Dickman, 2011), which might be considered in the soft. receiver.
- ✓ When Wide Area RTK, involving precise ionospheric corrections, is applied, the convergence time under full cold start is reduced to less than one third.

*Thank you*

# How GPS Works

(the most mature GNSS)

20.000km

We're somewhere on this sphere.

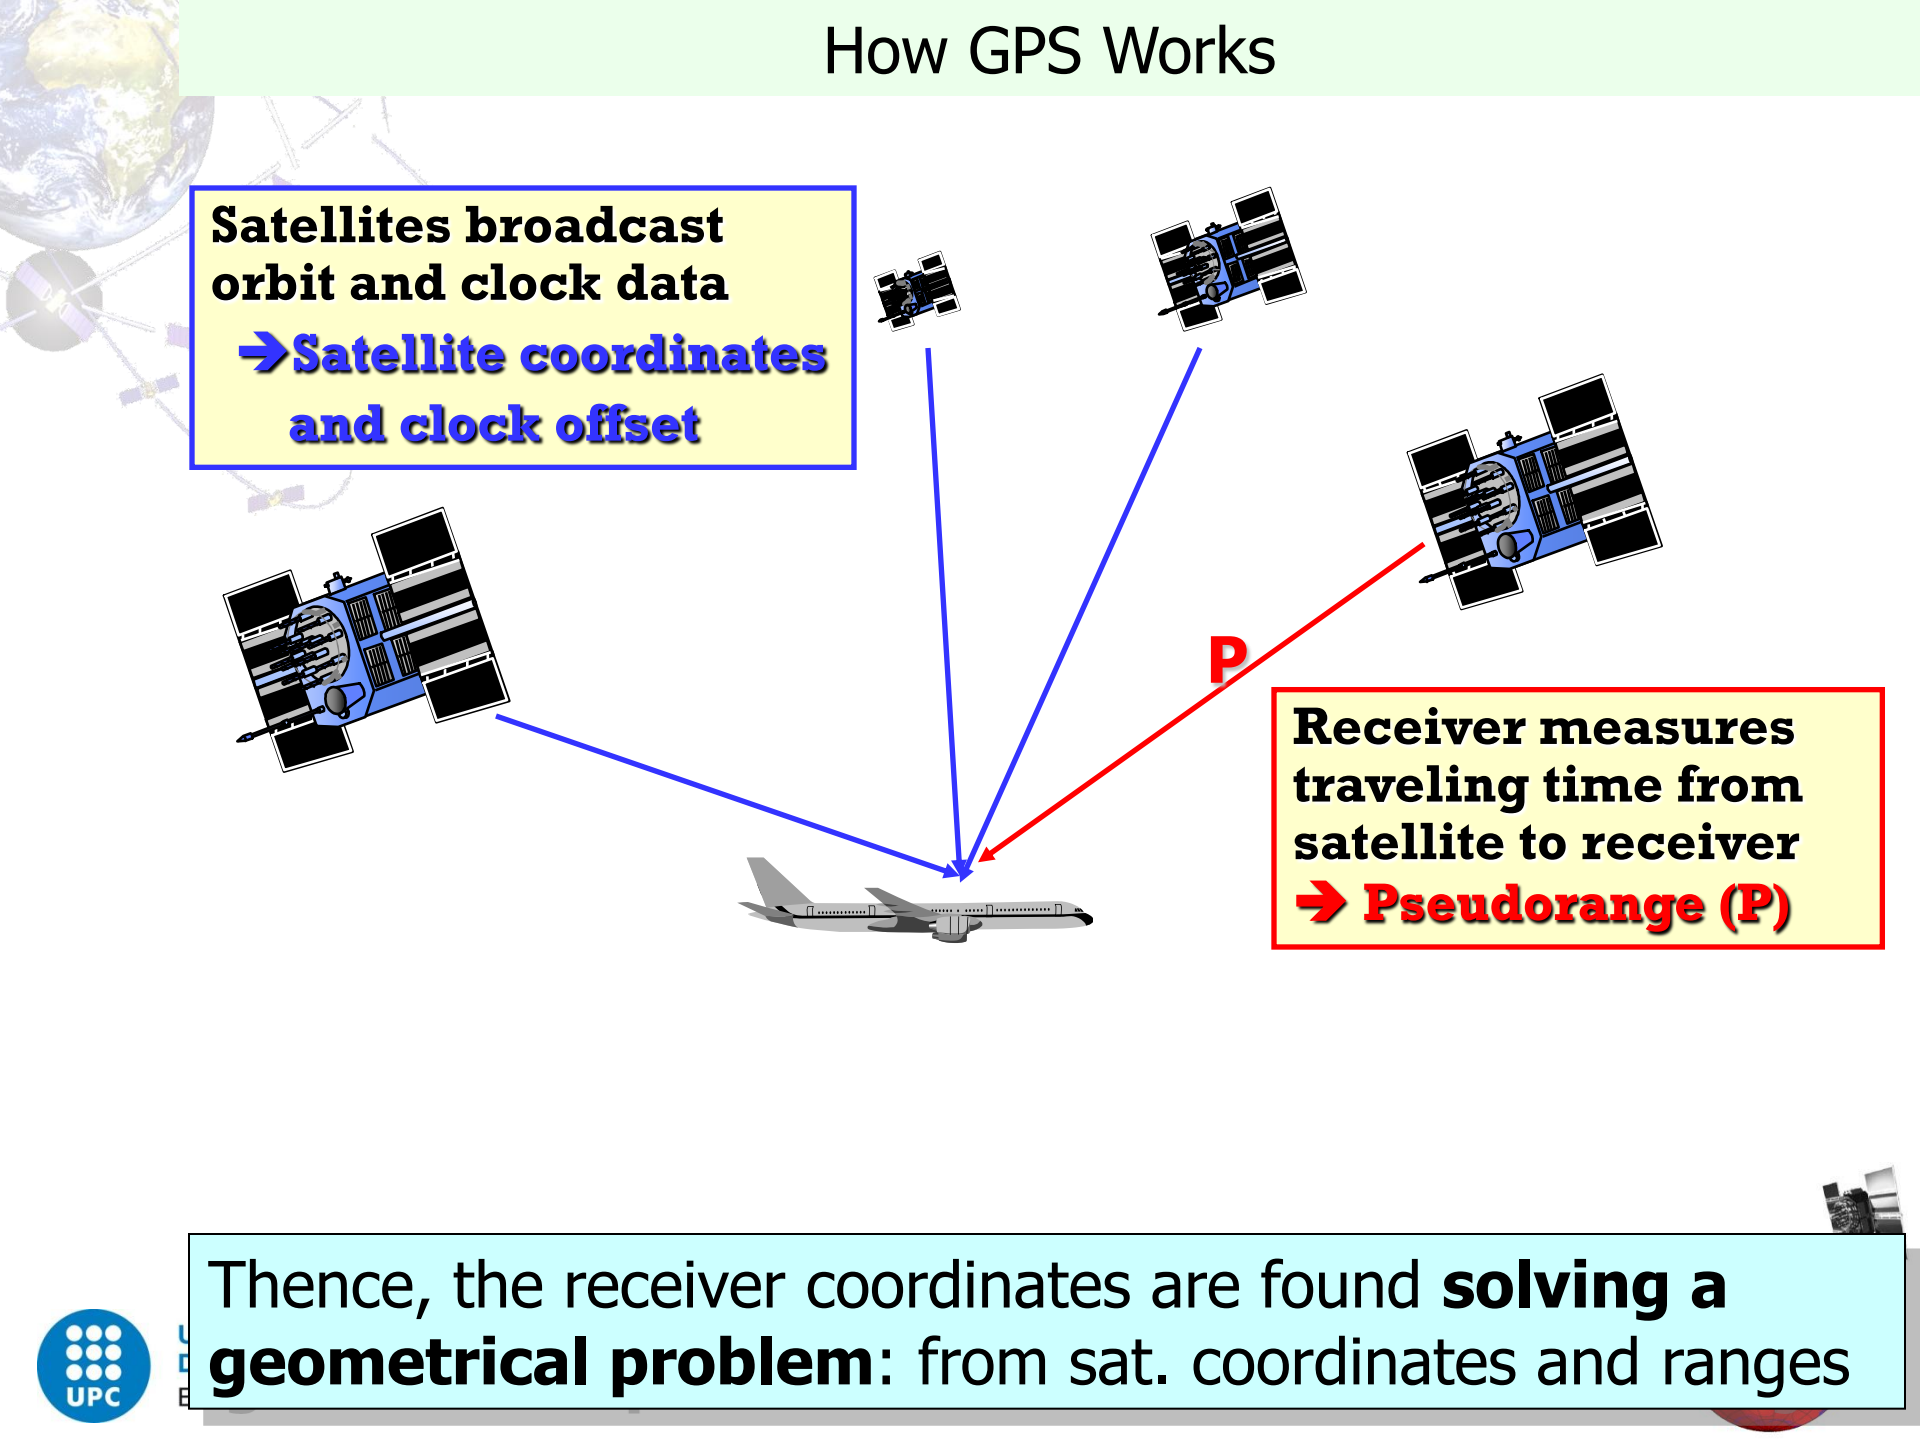

Two measurements puts us somewhere on this circle

Three measurements puts us at one of two points

One of the solutions is not on the Earth surface.

# How GPS Works

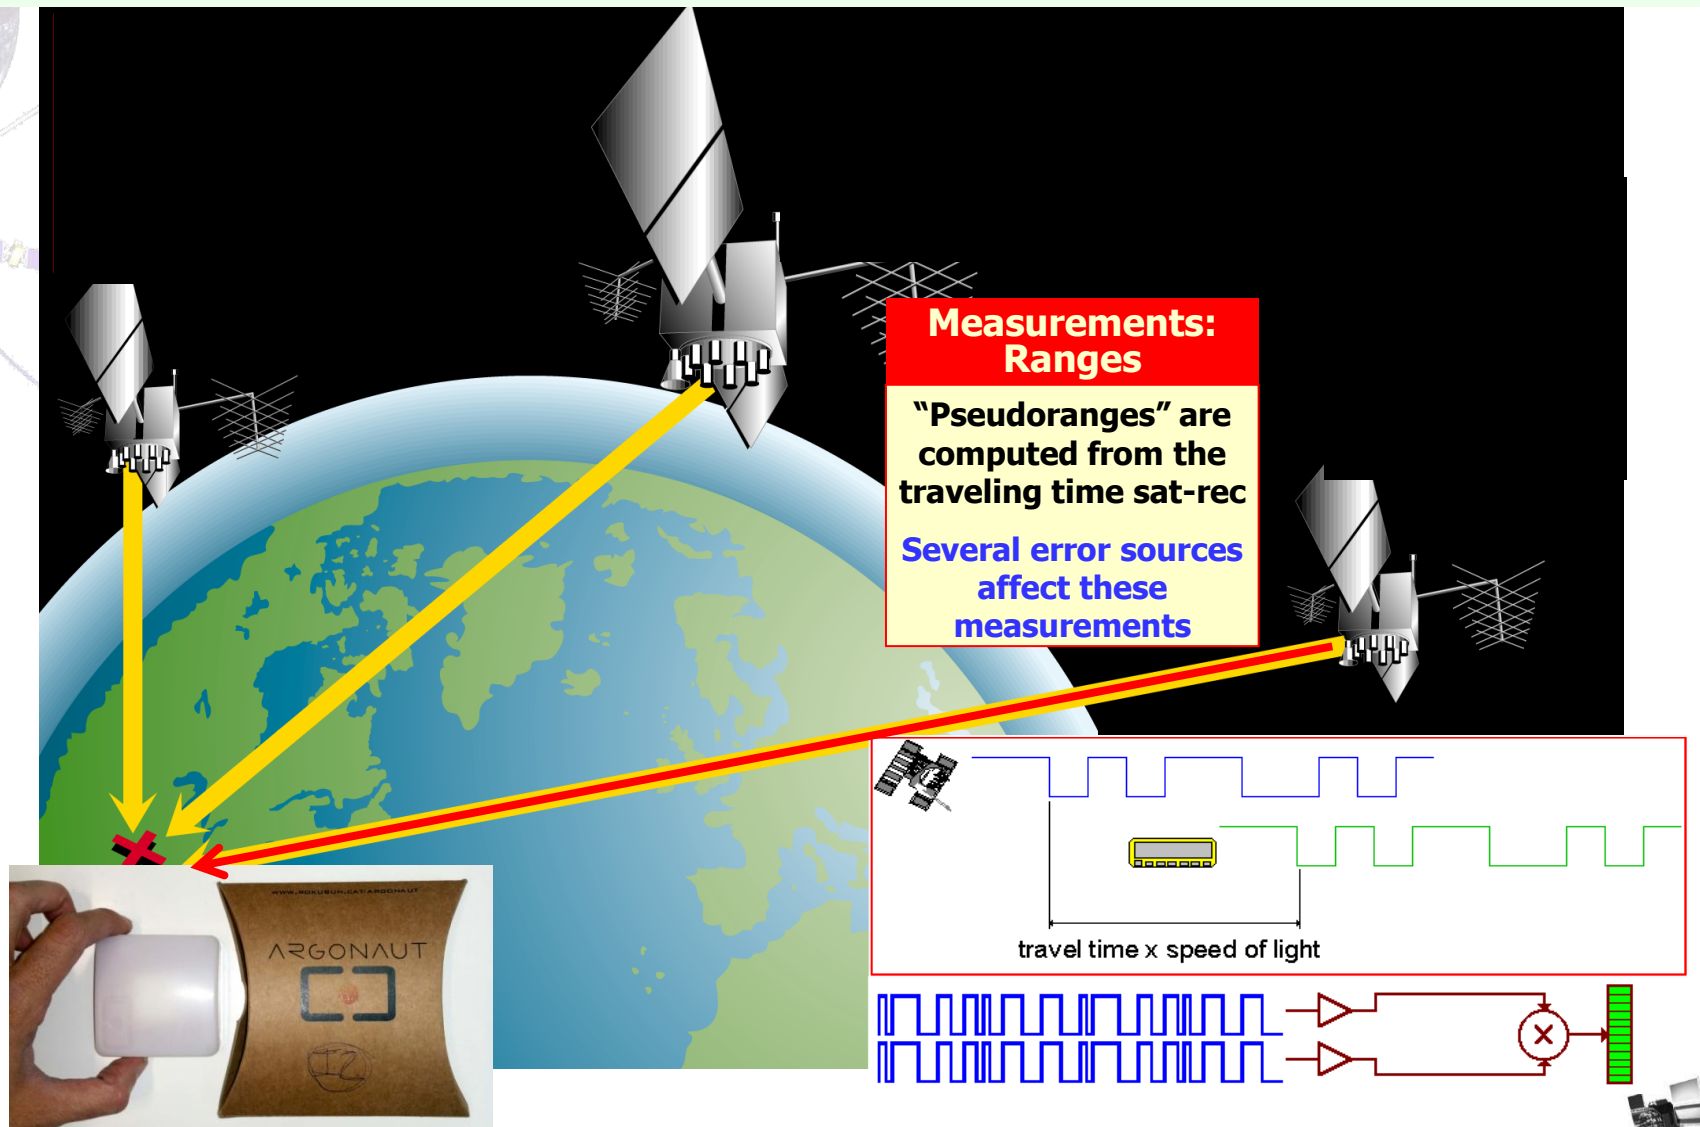

The diagram illustrates the GPS system. At the top left, a globe shows satellite orbits. Four GPS satellites are shown in the sky, each with solar panels and antennas. A commercial airplane is shown at the bottom, representing the receiver. Blue arrows point from three satellites to the airplane, while a red arrow points from the fourth satellite to the airplane, labeled with a red 'P'. Two text boxes provide further details: a yellow box on the left explains satellite broadcasts, and a red box on the right explains the pseudorange measurement.

Satellites broadcast orbit and clock data  
→ **Satellite coordinates and clock offset**

Receiver measures traveling time from satellite to receiver  
→ **Pseudorange (P)**

Thence, the receiver coordinates are found **solving a geometrical problem**: from sat. coordinates and ranges

# How GPS Works

1. Code or pseudorange: This measurement is given by the apparent travel time  $\tau$  of the EM signal propagated from GPS transmitter to receiver, scaled by the speed of light in the vacuum,  $c$ . This value can be partially considered as a range, i.e., a pseudorange  $\tilde{\rho}$ :

$$P \equiv c\tau = \tilde{\rho} \quad (3)$$

2. Carrier phase: This measurement is computed in the receiver by continuously integrating the frequency Doppler shift, primarily due to the relative velocity, clocks, and tropospheric and ionospheric drifts. This value is scaled in unit lengths in such a way that it represents the pseudorange  $\tilde{\rho}$  and basically refers to the last time the carrier phase was locked by the receiver  $t_L$  (i.e., the pseudorange change since the last “cycle-slip” or the first acquisition epoch).

$$\int_{t_L}^t \dot{\tilde{\rho}} dt = -\frac{c}{f} \int_{t_L}^t \delta f \cdot dt. \quad (5)$$

Thus, the carrier phase is finally defined as:

$$L \equiv -\lambda \int_{t_L}^t \delta f \cdot dt = \tilde{\rho}(t) - \tilde{\rho}(t_L) = \tilde{\rho} + B_f, \quad (6)$$

where  $B_f$  is the carrier phase ambiguity for frequency  $f$  and  $\lambda = c/f$  is the corresponding carrier wavelength.

# Carrier phase ambiguity fixing: key for precise navigation

- The code measurements (such as C/A) are accurate (psedorange) but not precise (measurement noise and multipath  $> \sim 1$  m).
- The carrier phase measurements are not accurate (unknown ambiguity = pseudorange at phase lock) but very precise (measurement noise and multipath  $< 1$ cm).
- To get real-time precise positioning the carrier phase ambiguities should be fixed in real-time.
- The differential approach is quite convenient in this task.

The characteristic wavelengths in GPS are those associated with the corresponding carriers:  $f_1 = 154f_0$  for  $L_1$  and  $f_2 = 120f_0$  for  $L_2$ , derived from the fundamental frequency  $f_0 = 10.23$  MHz, i.e.,  $\lambda_1 \simeq 0.19$  m and  $\lambda_2 \simeq 0.24$  m. For phase measurements, the error is approximately at millimeter level ( $\simeq 0.01\lambda$ ), between two to three orders of magnitude smaller than the code measurement error. This fact, along with a much smaller multipath (less than  $\frac{\lambda}{4} \simeq 0.05$  m, typically at the level of few millimeters) due to the beat phase characteristics, makes this observable the most suitable for high-accuracy applications in general and for ionospheric sounding in particular. Indeed, precise navigation and ionospheric determinations are usually made with carrier phase measurements. However, to best utilize the carrier phase, the large associated unknown (carrier phase ambiguity) must be properly solved, typically as an unknown parameter (treated as a Gaussian random variable) in a given continuous arc of data (with no cycle-slips, i.e., with no loss of lock on the signal).

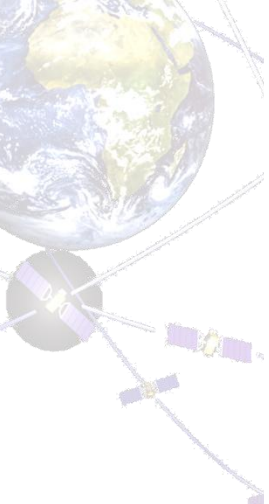

$$P_m = \rho + c(dt - dt') + \frac{40.309}{f_m^2} S + T + D_m + D'_m \quad (15)$$

and

$$L_m = \rho + c(dt - dt') - \frac{40.309}{f_m^2} S + T + B_m + \frac{c}{f_m} \phi \quad (16)$$

$$S = \int_{r_T}^{r_R} N_e dl$$

here, in SI units,  $P_m$  and  $L_m$  represent the code and phase measurements, respectively, of the transmitter by the receiver at a given time  $t$ , after correcting for the corresponding antenna phase center offset and vector;  $\rho$ ,  $dt$ ,  $dt'$ ,  $S$  and  $T$  are the corresponding distance, receiver and transmitter clock errors, slant total electron content and slant tropospheric delay respectively;  $f_m$  refers to the frequency of the carrier “ $m$ ”;  $D_m$  and  $D'_m$  are the receiver and transmitter inter-frequency differential code biases (DCBs), respectively, for the given frequency also referred to as interfrequency bias, IFB (note that the “prime” symbol represents terms associated with the GNSS transmitter/satellite). Finally,  $\phi$  represents the relative rotation, in cycles, between the transmitter and receiver antennas (the wind-up effect associated with the

The basic relationships defining  $B_c$  and  $B_w$  ambiguities are:

$$B_c = \frac{f_1^2 B_1 - f_2^2 B_2}{f_1^2 - f_2^2},$$

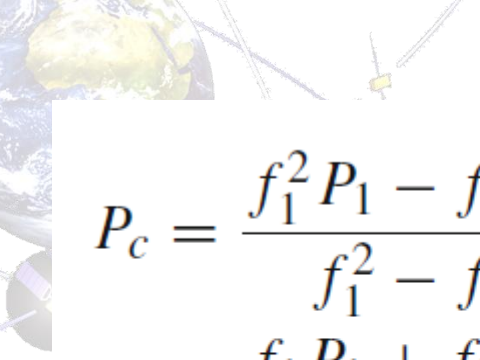

$$B_w = \frac{f_1 B_1 - f_2 B_2}{f_1 - f_2}$$

**Dual-frequency GPS combinations: The iono.-free (geometric) ones,  $L_c$ ,  $P_c$ , and the iono.- & geom.free one, Melbourne-Wubben,  $MW=L_w-P_n$**

associated with the corresponding ionospheric-free and widelane carrier phase combinations:

$$L_c = \frac{f_1^2 L_1 - f_2^2 L_2}{f_1^2 - f_2^2}, \quad (21)$$

$$L_w = \frac{f_1 L_1 - f_2 L_2}{f_1 - f_2}. \quad (22)$$

$$P_c = \frac{f_1^2 P_1 - f_2^2 P_2}{f_1^2 - f_2^2}, \quad (23)$$

$$P_n = \frac{f_1 P_1 + f_2 P_2}{f_1 + f_2}.$$

In this last case, the Melbourne-Wübbena combination  $M_w = L_w - P_n$  can be formed. From here on, it is straightforward to deduce that the phase ambiguity  $B_I$  of the ionospheric combination of carrier phases  $L_I = L_1 - L_2$  (see Eq. 17) can be computed from  $B_c$  and  $B_w$  (which helps in the determination of the electron content in ionospheric models based on permanent GNSS receiver data; see the corresponding subsection below):

$$B_I \equiv B_1 - B_2 = \frac{\lambda_1 \lambda_2}{\lambda_w \lambda_n} [B_w - B_c] \quad (25)$$

considering

$$B_w = M_w - \frac{\lambda_w \lambda_n}{\lambda_1 \lambda_2} (D_I + D'_I) \quad (26)$$

$$P_m = \rho + c(dt - dt') + \frac{40.309}{f_m^2} S + T + D_m + D'_m \quad (15)$$

and

$$L_m = \rho + c(dt - dt') - \frac{40.309}{f_m^2} S + T + B_m + \frac{c}{f_m} \phi \quad (16)$$

$$S = \int_{r_T}^{r_R} N_e dl$$

Let's **focus on the frequency dependent term due to the ionosphere** (an opportunity as **extra condition for precise RT positioning, and GNSS as geophysical RT sounder**)

here, in SI units,  $P_m$  and  $L_m$  represent the code and phase measurements, respectively, of the transmitter by the receiver at a given time  $t$ , after correcting for the corresponding antenna phase center offset and vector;  $\rho$ ,  $dt$ ,  $dt'$ ,  $S$  and  $T$  are the corresponding distance, receiver and transmitter clock errors, slant total electron content and slant tropospheric delay respectively;  $f_m$  refers to the frequency of the carrier “ $m$ ”;  $D_m$  and  $D'_m$  are the receiver and transmitter inter-frequency differential code biases (DCBs), respectively, for the given frequency also referred to as interfrequency bias, IFB (note that the “prime” symbol represents terms associated with the GNSS transmitter/satellite). Finally,  $\phi$  represents the relative rotation, in cycles, between the transmitter and receiver antennas (the wind-up effect associated with the

**Abstract** High precision Global Navigation Satellite Systems (GNSS) positioning and time transfer require correcting signal delays, in particular higher-order ionospheric (I2+) terms. We present a consolidated model to correct second- and third-order terms, geometric bending and differential STEC bending effects in GNSS data. The model has been implemented in an online service correcting observations from submitted RINEX files for I2+ effects. We performed GNSS data processing with and without including I2+ corrections, in order to investigate the impact of I2+ corrections on GNSS products. We selected three time periods representing different ionospheric conditions. We used GPS and Global Navigation Satellite System observations from a global network and two regional networks in Poland and Brazil. We estimated satellite orbits, satellite clock corrections, Earth rotation parameters, troposphere delays, horizontal gradients, and receiver positions using global GNSS solution, Real-Time Kinematic (RTK), and Precise Point Positioning (PPP) techniques. The satellite-related products captured most of the impact of I2+ corrections, with the magnitude up to 2 cm for clock corrections, 1 cm for the along- and cross-track orbit components, and below 5 mm for the radial component. The impact of I2+ on troposphere products turned out to be insignificant in general. I2+ corrections had limited influence on the performance of ambiguity resolution and the reliability of RTK positioning. Finally, we found that I2+ corrections caused a systematic shift in the coordinate domain that was time- and region-dependent and reached up to −11 mm for the north component of the Brazilian stations during the most active ionospheric conditions.

# Dual-frequency GPS combinations: The geometry-free (ionospheric) ones: LI, PI

$$L_I \equiv L_1 - L_2 = \alpha \cdot S - \beta \cdot \phi + B_I, \quad (17)$$

$$P_I \equiv P_2 - P_1 = \alpha \cdot S + D_I + D'_I + \epsilon_M + \epsilon_T, \quad (18)$$

where  $\alpha = 40.309 \left( \frac{1}{f_2^2} - \frac{1}{f_1^2} \right) = 1.05 \cdot 10^{-17} \text{ m}^3$ ,  $\beta = c \left( \frac{1}{f_2} - \frac{1}{f_1} \right) = 0.054 \text{ m}$ ,  $B_I = B_1 - B_2$ ,  $D_I = D_2 - D_1$  and  $D'_I = D'_2 - D'_1$ .<sup>2</sup> In this case, we also made explicit the two main components of the measurement error, both corresponding to the code: the multipath code error  $\epsilon_M$  and the thermal noise measurement error  $\epsilon_T$ . Typically, the wind-up term  $\beta \cdot \phi$  is a centimeter-level term. For the permanent receivers, this term can be corrected very accurately from their coordinates and orbital information, and it is not discussed explicitly herein.

# Estimating the ionospheric electron content...

The GNSS ionospheric measurements are an excellent input for estimating the ionospheric electron content distribution, for instance performing tomography (layout of its implementation in TOMION UPC-IonSAT software).

$$L_I = STEC + B_I = \int_{REC}^{SAT} N_e dl + B_I = \sum_i \sum_j \sum_k (N_e)_{i,j,k} \Delta s_{i,j,k} + B_I$$

# GPS and the Ionosphere

The GPS signals are affected by the free electrons: carrier phase advance and code/pseudorange delays.

The UV (and X) Solar radiation ionizes the region above 50-100 km: **Ionosphere** (to 1000 km) and Protonosphere/Plasmasphere (above 1000 km).

# Ionospheric delay at a glance

$$\delta R_{IONOSPHERE}[m] \simeq 0.4 \frac{STE C[TECU]}{f^2[GHz^2]}$$

$$1 TECU = 10^{16} el./m^2 \simeq 15 cm \simeq 0.5 ns \text{ in } L_1$$

**Typical noon VTEC ionospheric values ranges at mid latitude from 20 to 80 TECU, depending on the Solar cycle and season (3 to 12m in L1, 0.1 to 2 m in C band) (\*) 1 TECU=16 cm at L1**

# Equatorial anomalies and E cross B drift

Assuming only electric and magnetic fields acting on the charged particles, the component of  $\vec{E}$  along  $\vec{B}$  will vanish (it is the only force acting in this direction, generating a polarized field which suppress the external one).

$$\underbrace{\langle m\dot{\vec{v}} \rangle = q\vec{E} + q\vec{u}_E \times \vec{B}}_{\times \vec{B}} = \vec{0}$$

$$\vec{0} = q\vec{E} \times \vec{B} + q \left[ \underbrace{\vec{u}_E \cdot \vec{B}}_0 \vec{B} - B^2 \vec{u}_E \right]$$

$$\vec{u}_E = \frac{1}{B^2} \vec{E} \times \vec{B}$$

Being  $u_E$  the displacement velocity generated by the E cross B drift. For a general force  $\vec{F}$ :

$$\vec{u}_F = \frac{1}{qB^2} \vec{F} \times \vec{B}$$

**Abstract** Plasma bubbles are prevalent features of the equatorial/low-latitude ionosphere which are seldom observed at middle and high latitudes. Understanding the influence of geomagnetic storms on plasma bubbles' migration to higher latitudes is an important space weather topic, since a geomagnetic storm is an important phenomenon of space weather. This paper reports on the first observations of postsunset/evening midlatitude plasma bubbles in the European sector during the main phase of severe storms ( $Dst \leq -200$  nT) on 6 April 2000 and 11 April 2001. Plasma depletions observed in Global Navigation Satellite System total electron content measurements are confirmed with those observed from in situ Defense Meteorological Satellite Program ion density measurements. The results show that the plasma bubbles were migrating north at virtual speeds of 400 m/s and on each of the storm days they extended as far north as  $\sim 42^\circ$  (geographic latitude). It is estimated that the plasma bubbles may have grown to a maximum apex height of approximately 4000 km. During the time of bubble occurrence, the evening midlatitude plasma was enhanced and the equatorial ionization anomaly extended to European midlatitudes. In addition, evidence of the upward plasma motion was found in ionosonde  $h_m F_2$  and  $h'F$  measurements, while the interplanetary electric field  $E_y$  was enhanced. This was found to suggest that the possible mechanism for the enhancement of midlatitude plasma and subsequent midlatitude plasma bubbles occurrence was the eastward penetration electric field associated with  $B_z$  southward turning.

# STEC can be affected by Travelling Ionospheric Disturbances

PRN01 from USUD: Lon=138 deg, Lat=36 deg (LT=UT+9.22 hours)

**The ionospheric waves can produce STEC variations of several TECU (more than 20 cm at L1, and up to several cm at C-band), but with different phases at different locations, diffculting the interpolation of the ionospheric corrections.**

**Abstract** In this paper, the authors summarize a simple and efficient approach developed to mitigate the problem in precise Global Navigation Satellite Systems (GNSS) positioning originated by the most frequent ionospheric wave signatures: the medium-scale traveling ionospheric disturbances (MSTIDs). The direct GNSS Ionospheric Interferometry technique (hereinafter dGII), presented in this paper, is applied for correcting MSTID effects on precise Real Time Kinematic (RTK) and tropospheric determination. It consists of the evolution of the former climatic Differential Delay Mitigation Model for MSTIDs (DMTID), for real-time conditions, using ionospheric data from a single permanent receiver only. The performance is demonstrated with networks of GNSS receivers in Poland, treated as users under real-time conditions, during two representative days in winter and summer seasons (days 353 and 168 of year 2013). In range domain, dGII typically reduces the ionospheric delay error up to 10–90% of the value when the MSTID mitigation model is not applied. The main dGII impact on precise positioning is that we can obtain reliable RTK position faster. In particular, the ambiguity success rate parameter increases, from 74% to 83%, with respect to the original uncorrected observations. The average of time to first fix is shortened from 30 s to 13 s. The improvement in troposphere estimation, due to any potential impact of the MSTID mitigation model, was most difficult to demonstrate.

<sup>1</sup>Department of Physics, Indian Institute of Technology (BHU), Varanasi, India, <sup>2</sup>Departament Matemàtica Aplicada IV, IonSAT res. group, Universitat Politècnica de Catalunya, Barcelona, Spain, <sup>3</sup>Departament de Teoria del Senyal i Comunicacions, TALP res. group, Universitat Politècnica de Catalunya, Barcelona, Spain

**Abstract** In this manuscript, the authors show how the Global Navigation Satellite Systems, GNSS (exemplified in the Global Positioning System, GPS), can be efficiently used for a very different purpose from that for which it was designed as an accurate Solar observational tool, already operational from the open global GPS measurements available in real-time, and with some advantages regarding dedicated instruments onboard spacecraft. The very high correlation of the solar extreme ultraviolet (EUV) photon flux rate in the 26–34 nm spectral band, obtained from the solar EUV monitor instrument onboard the SOHO spacecraft during Solar flares, is shown with the GNSS solar flare activity indicator (GSFLAI). The GSFLAI is defined as the gradient of the ionospheric vertical total electron content rate versus the cosine of the Solar zenith angle in the day hemisphere (which filters out nonsolar over ionization), and it is measured from data collected by a global network of dual frequency GPS receivers (giving in this way continuous coverage). GSFLAI for 60 X class flares, 320 M class flares, and 300 C class flares, occurred since 2001, were directly compared with the EUV solar flux rate data to show existing correlations. It was found that the GSFLAI and EUV flux rate present the same linear relationship for all classes of flares, not only the strong and medium intensity ones, X and M class, as in previous works, but also for the weakest C class solar flares, which is a remarkable result.

# The Ionospheric term in GPS

GPS signal is very sensitive to free electron distribution, which respond to the EM field, oscillating and generating a secondary EM wave which overimposes and change the velocity of the GPS signals (main iono. effect on GPS code and phase).

$$STE C = \int_{\vec{r}[GPS_{transmitter}]}^{\vec{r}[GPS_{receiver}]} N_e(\vec{r}, t) d\vec{r}$$

The Slant Total Electron Content (STEC) is defined as the surface electron density along the GPS ray path

The first order iono. term in GPS signal (99.9% of total) is proportional to Slant Total Electron Content (STEC) and to the inverse of the squared frequency (from Appleton equation, neglecting magnetic field and collisions).

$$\mathcal{I}_P \equiv \mathcal{I}_{PSEUDORANGE} = 40.3 \frac{STE C}{f^2}$$

$$\mathcal{I}_L \equiv \mathcal{I}_{CARRIER-PHASE} = -\mathcal{I}_P$$

MKS units

# From STEC to VTEC: Single layer model

Chapman profile:  $N_0 = 1 \times 10^{12} \text{ m}^{-3}$ ,  $h_m = 350 \text{ km}$ ,  $H = 100 \text{ km}$ ,  $X = 0$

**Effective Height**  
(Sun at zenith and assuming the slab thickness width,  $VTEC/N_0$ )

**One simple way of obtaining the VTEC from STEC is based on the assumption of electron content concentrated at one shell at fixed *effective height* ("single layer model").**

**But such effective height can change in terms of Local Time (daylight/night), latitude and geomagnetic activity.**

**You can see at right the effective height change in terms of the Sun-zenith angle predicted by the Chapman model.**

# Standard ("Lanyi") Ionospheric Mapping Function

$$STE C = M \cdot VTE C$$

$$M = \frac{1}{\sin E'} \left\{ \begin{array}{l} M = \frac{1}{\sin E'} \\ r \cos E = r' \cos E' \end{array} \right\} M = \frac{1}{\sin E'} \frac{1}{\sqrt{1 - \frac{r^2}{(r+h)^2} \cos^2 E}} \left\{ \begin{array}{l} VTE C = STE C \cdot \sqrt{1 - \frac{r^2}{(r+h)^2} \cos^2 E} \Rightarrow \end{array} \right.$$

$$\Rightarrow \underbrace{STE C \cdot \sin E}_{h \rightarrow 0^+} < VTE C < \underbrace{STE C}_{h \rightarrow +\infty}$$

### Key Points:

- A new electron density profile extrapolation technique (VCET), founded on First Principles, is presented showing a high performance
- VCET is simple and accurate: it is based on the linear behavior of the topside scale height, performing 6–20 times better than Chapman model
- The accuracy and extrapolation range, illustrated with FORMOSAT-3/COSMIC measurements, will be important for new radio-occultation missions like EPS-SG

**Abstract** The new radio-occultation (RO) instrument on board the future EUMETSAT Polar System-Second Generation (EPS-SG) satellites, flying at a height of 820 km, is primarily focusing on neutral atmospheric profiling. It will also provide an opportunity for RO ionospheric sounding, but only below impact heights of 500 km, in order to guarantee a full data gathering of the neutral part. This will leave a gap of 320 km, which impedes the application of the direct inversion techniques to retrieve the electron density profile. To overcome this challenge, we have looked for new ways (accurate and simple) of extrapolating the electron density (also applicable to other low-Earth orbiting, LEO, missions like CHAMP): a new Vary-Chap Extrapolation Technique (VCET). VCET is based on the scale height behavior, linearly dependent on the altitude above  $h_m F_2$ . This allows extrapolating the electron density profile for impact heights above its peak height (this is the case for EPS-SG), up to the satellite orbital height. VCET has been assessed with more than 3700 complete electron density profiles obtained in four representative scenarios of the Constellation Observing System for Meteorology, Ionosphere, and Climate (COSMIC) in the United States and the Formosa Satellite Mission 3 (FORMOSAT-3) in Taiwan, in solar maximum and minimum conditions, and geomagnetically disturbed conditions, by applying an updated Improved Abel Transform Inversion technique to dual-frequency GPS measurements. It is shown that VCET performs much better than other classical Chapman models, with 60% of occultations showing relative extrapolation errors below 20%, in contrast with conventional Chapman model extrapolation approaches with 10% or less of the profiles with relative error below 20%.

gAGE/UPC 24/07/01

# DIFFERENTIAL Positioning concept

- In baselines shorter than few tens of km, similar errors are expected in differential approach, cancelling-out (exactly for satellite clocks, approximately for GPS orbital errors and for ionospheric error). –
- The extension to longer baselines is a problem specially due to the ionospheric error (quite difficult to predict it accurately).

# Wide Area RTK in a nutshell: Basic equations on DDamb

Once  $\nabla\Delta N_\delta$  is fixed, it is possible to fix the  $L_1$  and  $L_2$  double-differenced integer ambiguities  $N_1$  and  $N_2$  for the reference stations, using a sufficiently accurate determination of the double-differenced ambiguity  $\nabla\Delta B_c$  of the ionospheric free combination  $L_c = (f_1^2 L_1 - f_2^2 L_2)/(f_1^2 - f_2^2)$ . The following relationships illustrate these steps:

$$\begin{aligned}\nabla\Delta B_c &= 0.5[\lambda_\delta \nabla\Delta N_\delta + \lambda_n \nabla\Delta(N_1 + N_2)] \\ \nabla\Delta(N_1 + N_2) &= \text{NI}[(2\nabla\Delta B_c - \lambda_\delta \nabla\Delta N_\delta)/\lambda_n] \\ \nabla\Delta N_1 &= 0.5[\nabla\Delta N_\delta + \nabla\Delta(N_1 + N_2)] \\ \nabla\Delta N_2 &= \nabla\Delta N_1 - \nabla\Delta N_\delta\end{aligned}\tag{3}$$

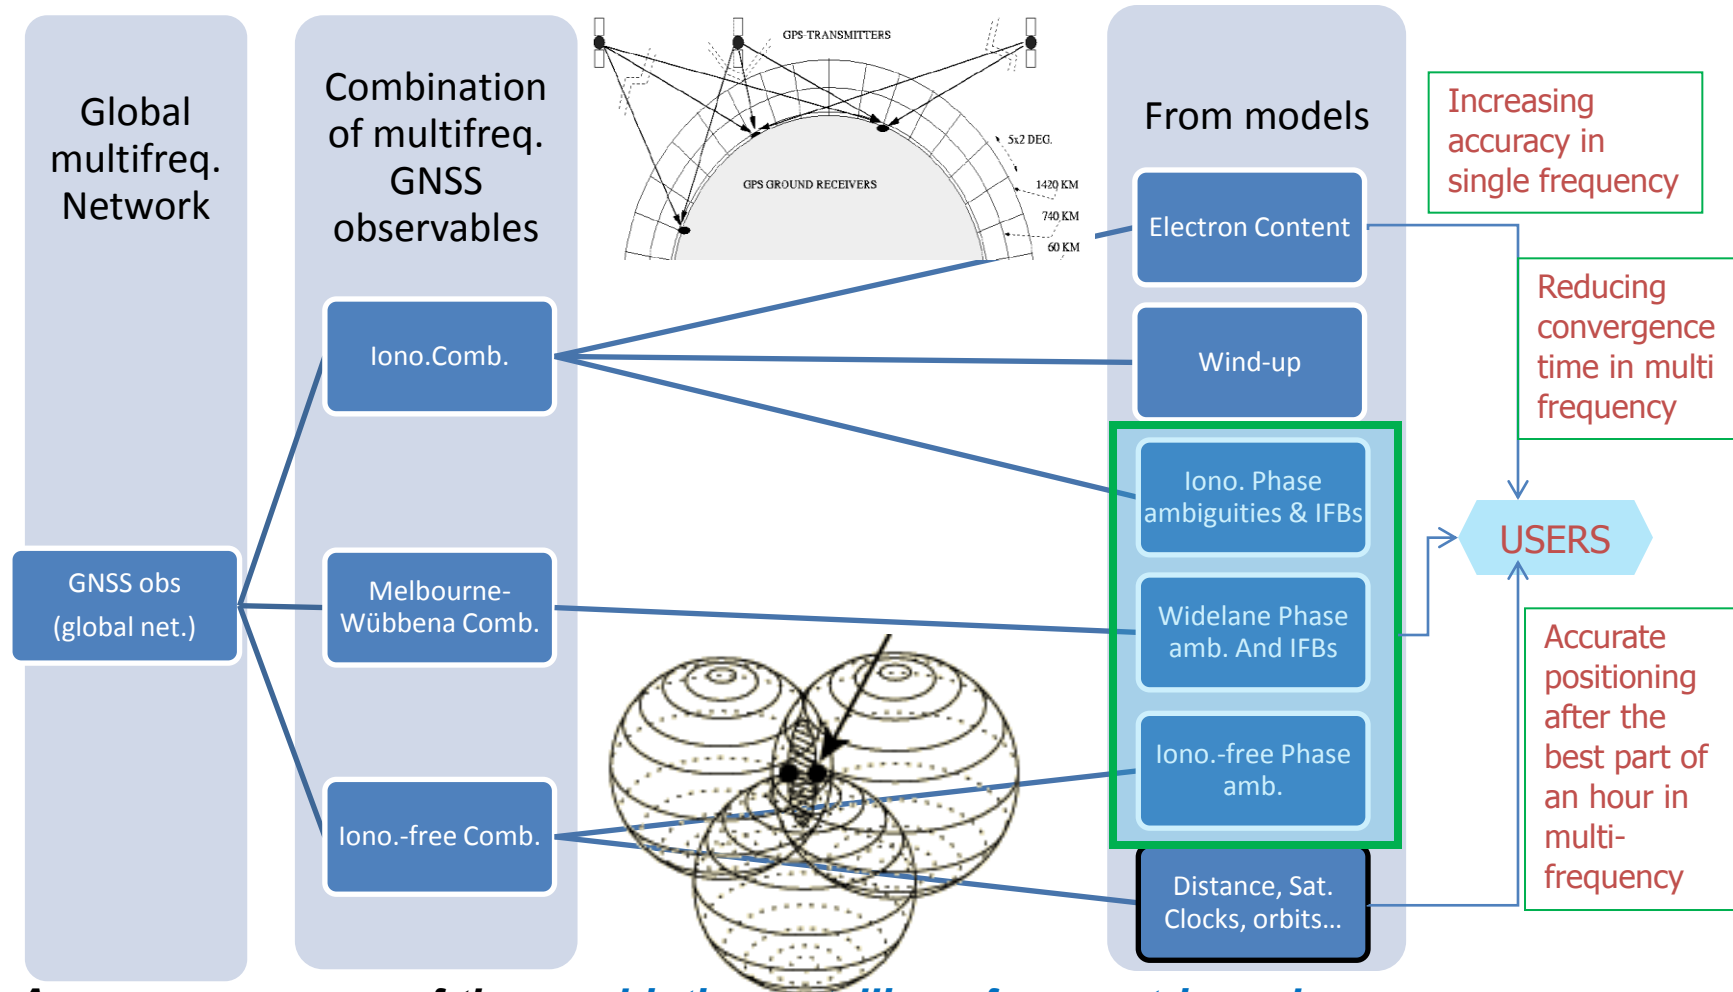

being  $\lambda_n = c/(f_1 + f_2) \simeq 10.7\text{cm}$  and NI the nearest integer. Hence, from  $\nabla\Delta N_1$  and  $\nabla\Delta N_2$ , the unambiguous double-differenced ionospheric slant total electron content, STEC, can be computed for the reference stations:

$$\alpha \nabla\Delta \text{STEC} = \nabla\Delta(L_1 - L_2) - (\lambda_1 \nabla\Delta N_1 - \lambda_2 \nabla\Delta N_2)\tag{4}$$

(Extracted from *Hernández-Pajares, M., Juan, J. M., Sanz, J., & Colombo, O. L. (2000). Application of ionospheric tomography to real-time GPS carrier-phase ambiguities resolution, at scales of 400–1000 km and with high geomagnetic activity. Geophysical Research Letters, 27(13), 2009-2012.*

Long-Baseline (hundreds Km) OTF Ambiguity Resolution

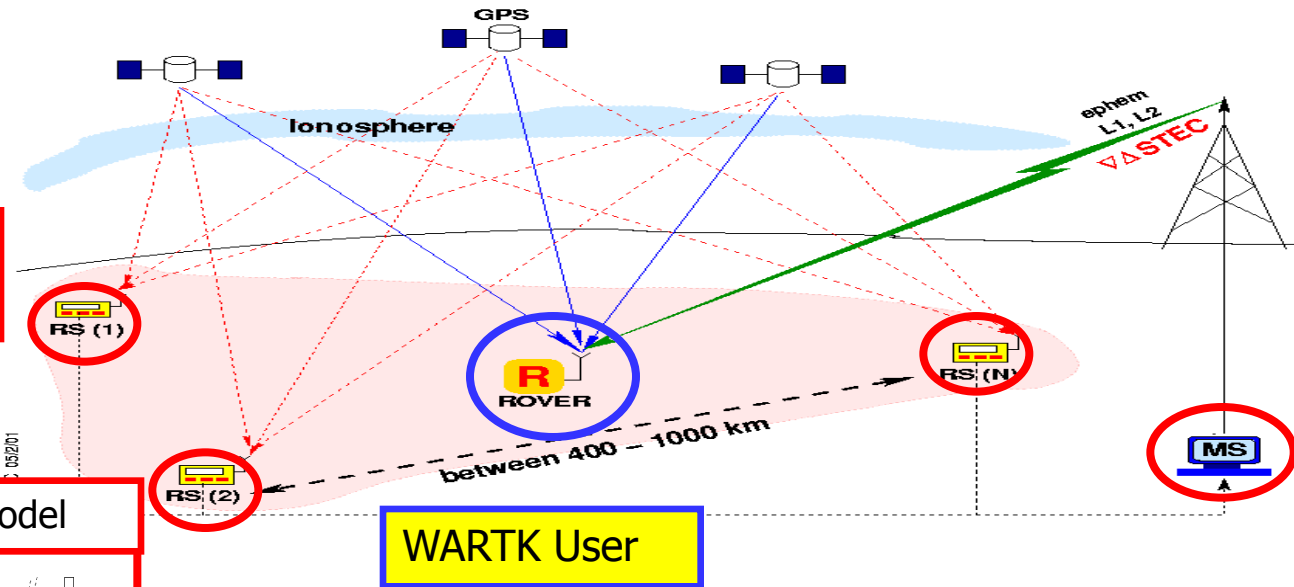

WARTK Central Processing Facility

Real-time Iono. model

$$L_1 = STEC + B_I = \int_{REC}^{\Delta T} N_e dl + B_I = \sum_i \sum_j \sum_k (N_e)_{i,j,k} \Delta s_{i,j,k} + B_I$$

Real-time geodetic model

WARTK User

- In Wide Area RTK the usual dependence of differential ionospheric refraction can be predicted with errors of few tenths of TECU (few cm in L1), also in difficult scenarios (**low latitude, Solar cycle maximum and distances of many hundreds of kilometres**, see Hernández-Pajares et al. 2000,2002).
- This allows centimeter-error-level navigation at distances up to hundreds of kilometers from the nearest GNSS reference site (at single epoch in Galileo and Modernized GPS).
- But “shorter scale” ionospheric perturbations (such as MSTIDs) –from tenths to few TECUs- can affect to GNSS precise positioning at both WARTK & RTK scales.

# The International GNSS Service (IGS)

- IGS provides continuous measurements of permanent worldwide receivers and derived products of highest quality, openly accesible via anonymous-ftp.
- The multi-frequency measurements are taken from hundreds of permanent GNSS receivers, each 30 seconds or either each second and in real-time, from the Artic to the Antartica, over all the continents, belonging to different contributing institutions.
- The provided products comprise satellite orbits and clocks, tropospheric delay, Global Ionospheric Maps – GIMS, among others.

# More details on IGS can be found in:

# GPS+ IGS: Global Iono. scanner

**Worldwide scanner of the Ionosphere that can be used to generate global VTEC maps**

# VTEC global maps: the cooperative effort in IGS

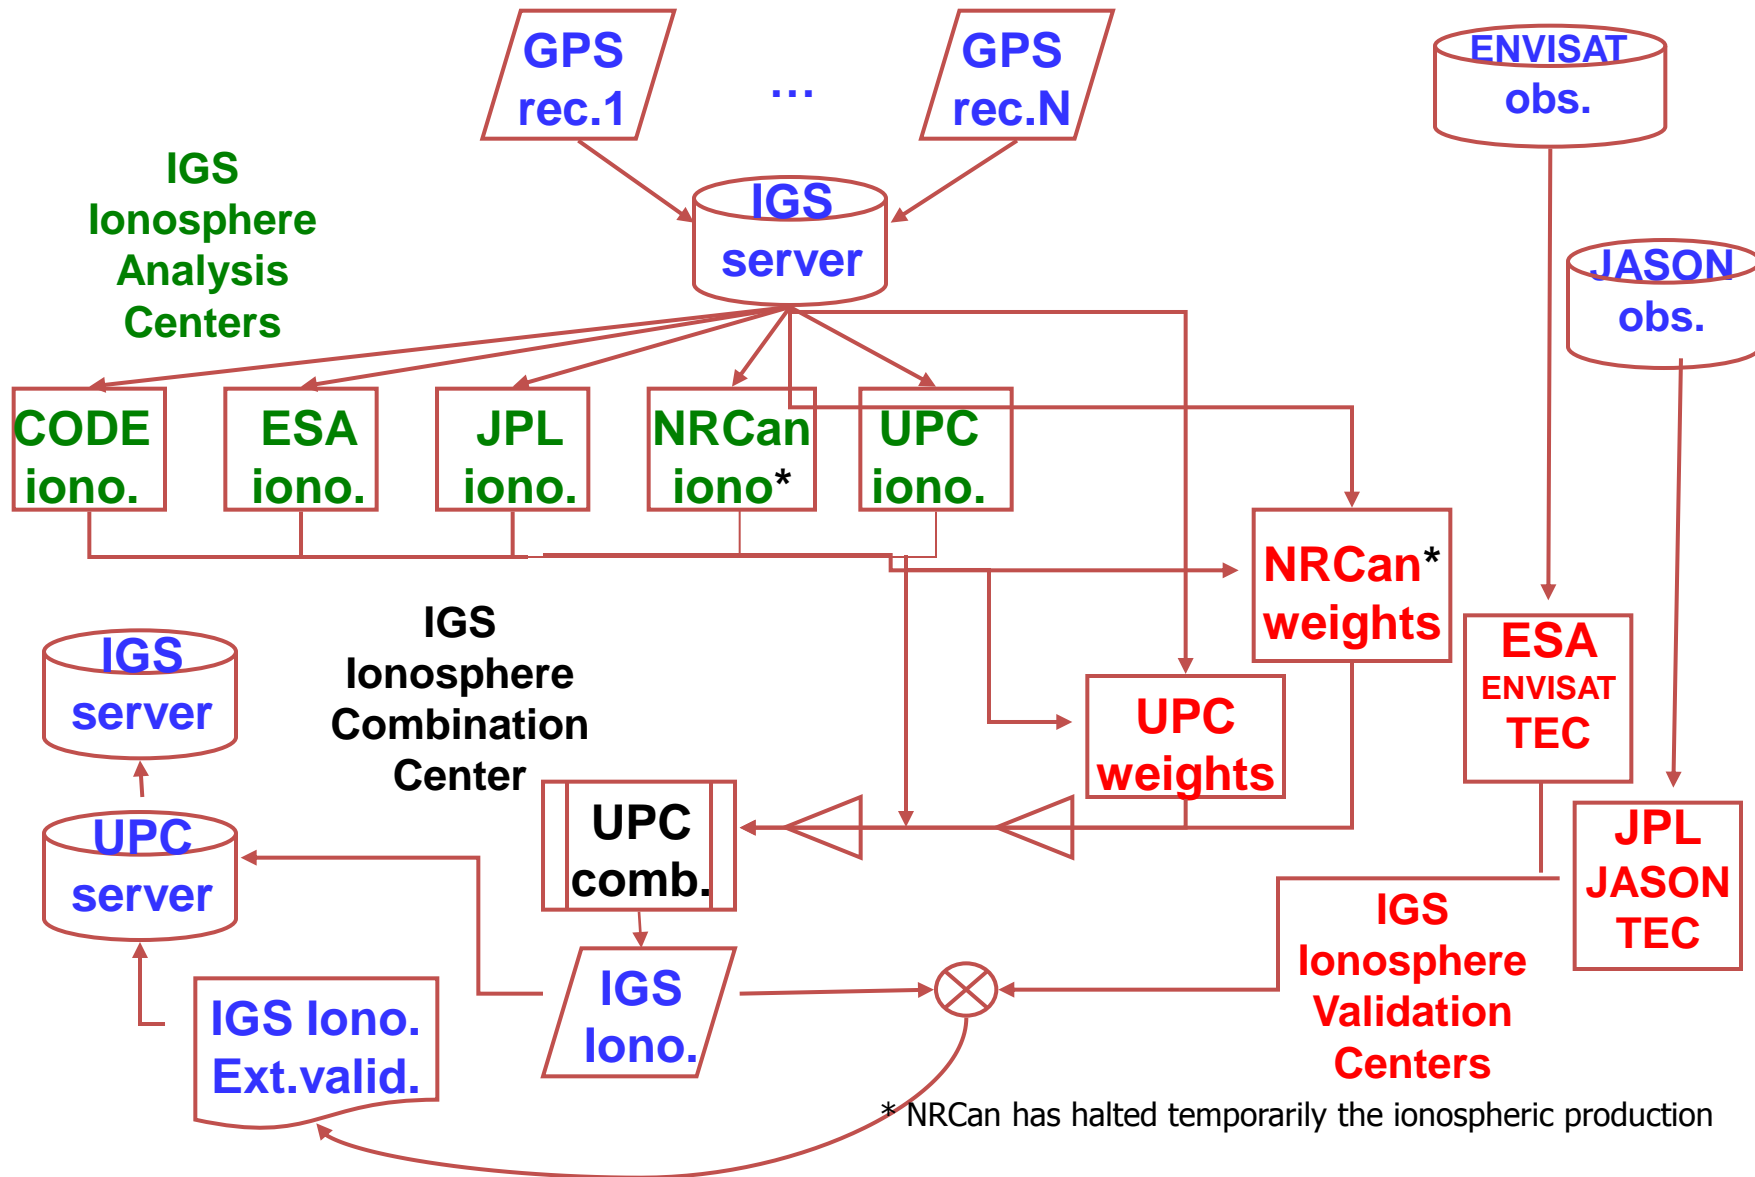

The IGS Ionosphere Working group started its activities in June 1998 with the main goal of a routinely producing IGS Global TEC maps (IGTEC). This is being done now with a latency of 11 days (**final product** –official-) and with a latency of less than 24 hours (**rapid product** –still unofficial-).

The IGS ionosphere product is a result of the combination of different Analysis Centers TEC maps by using weights computed from GPS data by Validation Centers, in order to get a more accurate product.

# IGS Final Ionosphere Flow-Chart

... and there is an standard format to distribute the VTEC maps: the IONEX format

# International GPS Service, IGS

**IGS directly manages more than about 350 permanent GPS stations, observing some 4-10 satellites at 30 sec rate: more than 250,000 STEC worldwide observations/hour, but there is lack of stations at the South and over the Seas**

# Determining VTEC in a global network: main problem of lack of data in South and Seas

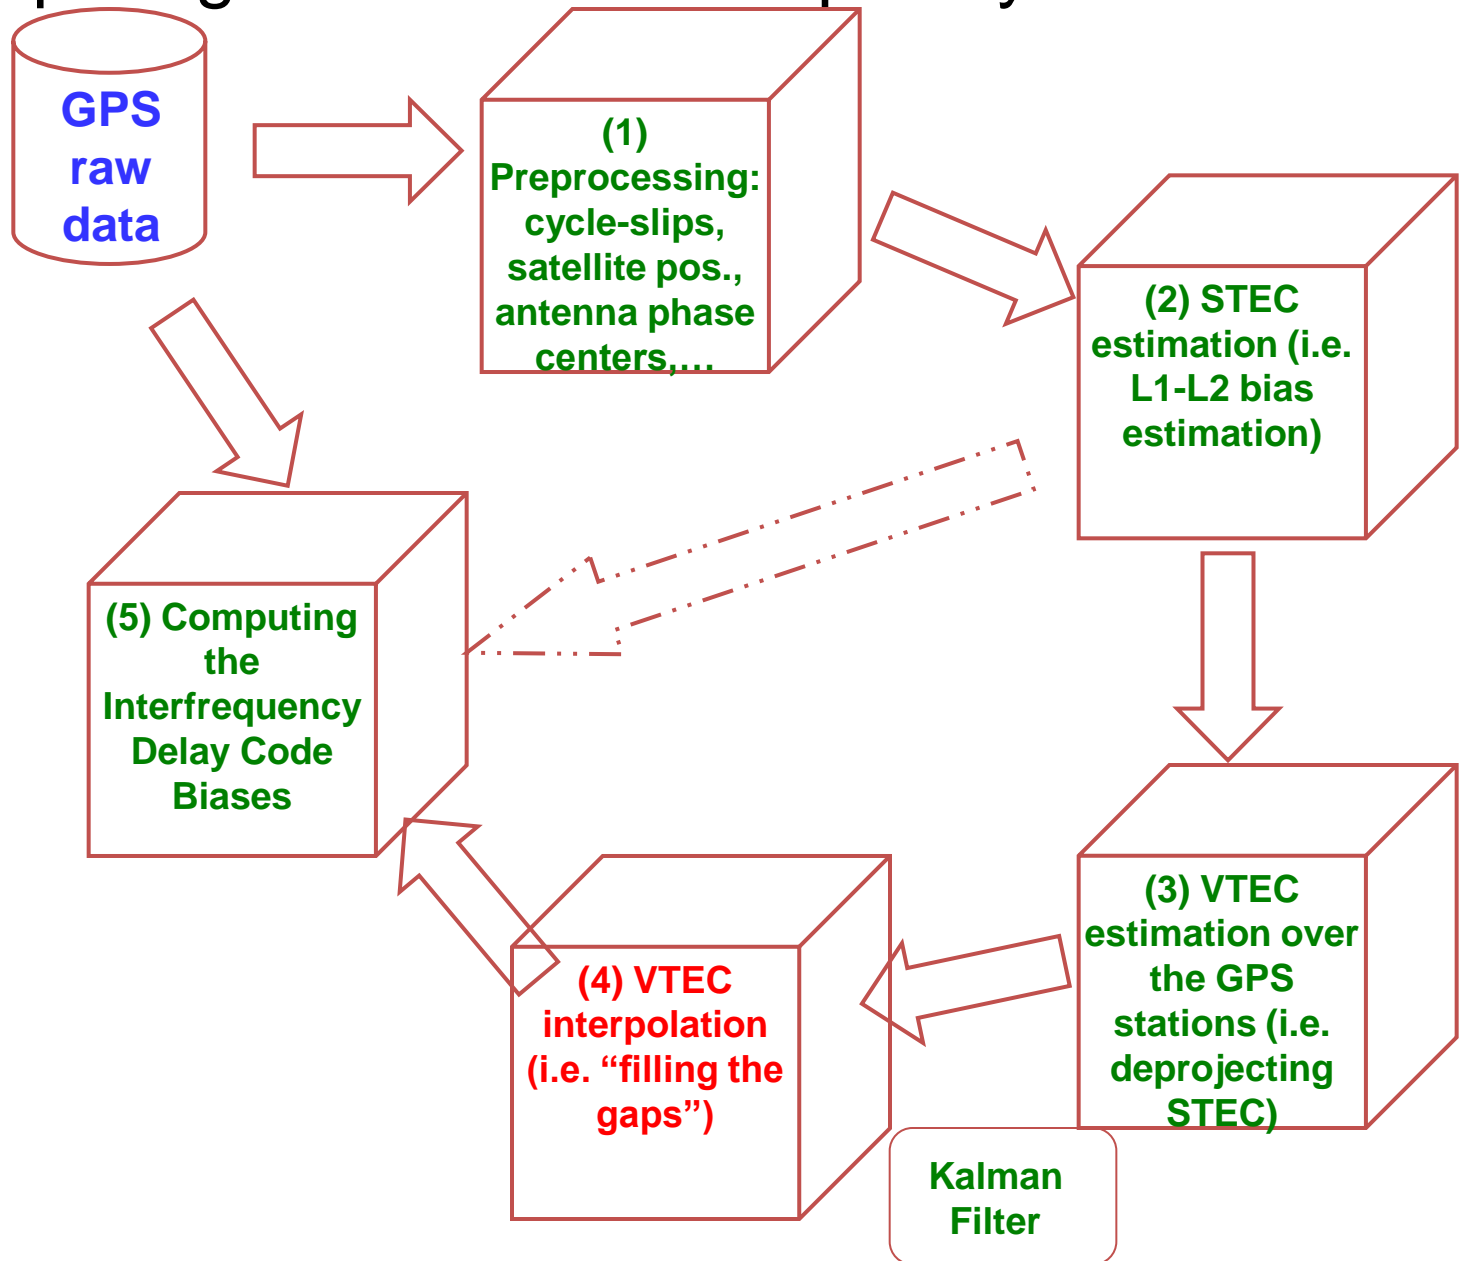

It can be seen the typical “holes” appearing in the first stage of the global maps computation (each 2 hours). This requires an optimum spatial-temporal interpolation technique to extend the estimates covering all the Ionosphere.

Lack of data in equatorial Africa and Atlantic, and in part of equatorial and southern Pacific, difficulting the detection of the equatorial anomalies (June 13, 2004).

# Computing Global VTEC maps: layout

# Example of IGS Final TEC map: 2003-347-00UT

Five Analysis Centers (CODE, ESA, JPL, NRCan and UPC) and 4 Validation Centers (JPL, ESA, NRCan and UPC) have been providing maps (at 2 hours x 5 deg. x 2.5 deg in UT x Lon. x Lat.), weights and external (dual-frequency altimetry-derived) TEC data.

Units: 0.1 TECUs

From such maps and weights the corresponding combination center (firstly ESA, and secondly UPC since Dec.2002) has produced the IGS TEC maps in ionex format.

# Example of comparison of IGS vs JASON: 2003-347 each 6 hours

Year: 2003; Day of Year: 347; UT: 1-3

Year: 2003; Day of Year: 347; UT: 7-9

Year: 2003; Day of Year: 347; UT: 13-15

Year: 2003; Day of Year: 347; UT: 19-21

JASON dual frequency altimeter provides a direct and independent VTEC below its orbit (1300 km) and over the oceans (worst case for GPS).

```

# Layout:

- 1) **[Motivation]** Precise Agriculture (PA) presentation (EU AUDITOR experiment)
- 2) **[Background]:** Brief introduction to main identified points of the presentation:
  - a) GPS fundamentals: pseudoranges and carrier phases (optional)
  - b) Ionospheric electron content
  - c) Wide Area Real-Time Kinematic
  - d) The International GNSS Service (*optional*)
- 3) **[One efficient operative system]** Quick introduction to Linux (*optional*)
- 4) **[New tools for learning and research]** IonSAT Tools (IT), emulating Real-Time (RT) as much as possible (presented on the PA AUDITOR experiment):
  - a) *gim2vtec.v2.scr*
  - b) *gimrnx2stec.v2.scr*
- 5) **[IT application to ECLIPSE, FLARE & GSTORM scenarios]** (*optional*).
- 6) **[Example of RT GPS-ionospheric system]:** UPC-IonSAT since 2012.
- 7) **[Monitoring of co-seismic generated ionospheric signals]:** Application of RT ionospheric sounding for potential Tsunami warnings), with GNSS dense (Tohoku and mid earthquakes, EQ) and sparse networks (Chile 2015 EQ).
- 8) **[Conclusions]**

**New IonSAT tools:**  
***gim2vtec.v2.scr* &**  
***gimrnx2stec.v2.scr***

- IonSAT tool `gim2vtec.v2.scr` : New Linux script for Vertical Total Electron Content (VTEC) extraction from Global Ionospheric Maps (GIM).
- IonSAT tool `gimrnx2stec.v2.scr`: New Linux script for Slant TEC (STEC) computation from GIM-calibrated GPS meas. Carrier phase prepro.
- The first suggested application is for the *motivating* AUDITOR experiment (June 13th, 2017) described in section 1, and for the baseline between reference and permanent receiver, similar to the tractor one.

# ***gim2vtec.v2.scr & gimrnx2stec.v2.scr @ AUDITOR***

- `ssh -X -p XXXXX ionsat-tools-userYY@chapman.upc.es`
- Where XXXXX is the port number (see blackboard) and YY the UserId # (since 01 to 20), and the password, given to you at the beginning of the corresponding laboratory session.
- `chapman:~% whoami`
- `chapman:~% cd ils`
- `chapman:~% pwd`
- `chapman:~% ls -l`
- `chapman:~% xedit run.IonSAT-lab_sessions.v4b.scr &`
- Uncomment (remove the first leading #) the three command lines for AUDITOR block, save and run the script:
- `chapman:~% ./run.IonSAT-lab_sessions.v4b.scr >& log.1 < /dev/null &`

# *gim2vtec.v2.scr & gimrnx2stec.v2.scr @ AUDITOR*

- chapman:~% tail -f log.1
- Once it is finished you can look at the selected results in form of plots:
- chapman:~% cd ~/ils/selected\_plots
- chapman:~% ./selected\_plots.scr
- chapman:~% ./selected\_plots.scr ftplink AUDITOR
- **Each ftp link can be pasted on the navigator at your local computer**, for low-bandwidth connections (for high-bandwidth you may wish to replace “ftplink” by “screen”).
- You should likely find these selected plots:

# STEC over BORJ from RINEX meas. calibrated with GIM UQRG

Year/Month/Day/DOY: 2017/06/12/163-2017/06/14/165

STEC [Rec.=borj, Lon.=6.666433125°, S.Lat.=53.394868985°] / TECU

# STEC over IJMU from RINEX meas. calibrated with GIM UQRG

Year/Month/Day/DOY: 2017/06/12/163-2017/06/14/165

STEC [Rec.=ijmu, Lon.=4.556064337°, S.Lat.=52.275883844°] / TEC

# Conclusions from STEC vs time plots?

- **Exercise 2:** Assess the answer previously provided to Exercise 1 referring to the expected range of STEC values (deduced from the VTEC ones).
- **Questions 3:** Is the GIM able to provide the right precision? Are the dual-frequency GPS carrier phase measurements alone able to provide the right accuracy? In such a context, how could be understood the GIM-calibration of dual-frequency measurements[\*]? How much **both** STEC differs?

$$[*] LI = L1 - L2 = \alpha \cdot S + BI + (\lambda1 - \lambda2) \cdot \varphi \Rightarrow$$

$$\Rightarrow BI\_calGIM = \langle LI - (\lambda1 - \lambda2) \cdot \varphi - \alpha \cdot S\_GIM \rangle \Rightarrow$$

$$\Rightarrow S\_L1calGIM = ( LI - BI\_calGIM - (\lambda1 - \lambda2) \cdot \varphi ) / \alpha$$

# Looking at the time evolution of the meridional VTEC (VTEC vs latitude) for the approximate longitude sector (E010°) of the Argentina/Chile border during the AUDITOR experiment

# VTEC vs latitude at E290° from UQRG GIM

Day 163, 2017 00.00 hours (uqrg)

# Conclusions from VTEC vs latitude plots?

- **Question 4:** Which is the approximate ratio between the highest and the lowest VTEC for different latitudes in the same meridian?
- **Question 5:** Why is systematically lower the VTEC at the South Pole than the VTEC at the North Pole?
- **Question 6:** Why the VTEC at both poles appear constant vs time?

**Looking the VTEC @ IJMU deprojected from the STEC derived GIM-alone and from different ionospheric combinations of GPS measurements, after UQRG-GIM calibration, vs the LI calibrated one:**

- GIM-alone and  $PI = P2 - P1$ .
- Single-frequency ionospheric measurements: Iono-Graphic1,  $IG1 = (P1 - L1)/2$  and Iono-Graphic2,  $IG2 = (P2 - L2)/2$ .

# VTEC derived from STEC over IJMU from: GIM & 2- and 1-freq. GPS meas. cal. with GIM (UQRG) vs LI=L1-L2 GIM cal.

Rec. ijmu elev. >= 0° during Year/Month/Day/DOY: 2017/06/12/163-2017/06/14/165

Rec. ijmu elev. >= 0° during Year/Month/Day/DOY: 2017/06/12/163-2017/06/14/165

Rec. ijmu elev. >= 0° during Year/Month/Day/DOY: 2017/06/12/163-2017/06/14/165

Rec. ijmu elev. >= 0° during Year/Month/Day/DOY: 2017/06/12/163-2017/06/14/165

# Conclusions from VTEC from STEC from GIM alone, and LI, PI, IG1 and IG2 UQRG-GIM calibrated?

- **Question 7:** Why the STEC derived from IG1 GIM calibrated is better than the corresponding PI one? The errors shown (compared with the most accurate and precise STEC from LI GIM calibrated) are compatible with the expected ones?
- **Question 8:** Why the STEC of IG2 is better than the one from IG1 in spite of the quality of P2 is worse than the quality of P1?
- **Question 9:** What would be the expected performance for IG5?

Looking for high absolute values of the double-time difference of  $LI=L1-L2$ ,  $d2LI$ , and the single-time diff. of  $MW=Lw-Pn$  as a sufficient condition to declare a carrier phase cycle-slip, i.e. Blewit method (IJMU during AUDITOR experiment)

➤  $d2LI = LI(t+dt) - LI(t) - (LI(t) - LI(t-dt)) = LI(t+dt) - 2LI(t) + LI(t-dt) = -2 (LI(t) - (LI(t+dt) + LI(t-dt)) / 2)$

➤ In other words,  $d2LI$  provide a simple ionospheric detrending method, subtracting to each point the linear prediction from the next and previous measurement.

➤ Melbourne-Wubbena does not need to be detrended (it is both ionospheric- and geometric-free, the problem is the pseudorange noise).

## Propagation of medium scale traveling ionospheric disturbances at different latitudes and solar cycle conditions

M. Hernández-Pajares,<sup>1</sup> J. M. Juan,<sup>1</sup> J. Sanz,<sup>1</sup> and A. Aragón-Ángel<sup>1,2</sup>

Received 2 December 2011; revised 6 April 2012; accepted 1 May 2012; published 4 July 2012.

[1] In this work, an extension in latitude range and time span with respect previous studies on Medium Scale Traveling Ionospheric Disturbances (MSTID) propagation, is presented. So far they have been basically studied at mid latitude and for limited periods (less than few years) at solar maximum conditions. This extension has been possible due to the availability of local Global Positioning System (GPS) networks at mid-north hemisphere (California), mid-south hemisphere (New Zealand), high and low latitudes (Alaska and Hawaii), for the last 13, 11, 7 and 4 years respectively. Optimal algorithms specially suitable for mass data processing have been used, such as the Single Receiver Medium Scale Traveling Ionospheric activity index (SRMTID) and the phase difference method for MSTID propagation estimation. The results reveal that several of the main MSTID climatological trends at mid latitude are also shared at low and high latitude, also modulated in intensity also by the Solar Cycle. This is the case for local fall/winter day-time equatorward propagated MSTIDs with typical velocities and wavelengths of 150–250 m/s and 100–300 km respectively. Moreover the comparison of MSTID propagation estimation using different techniques, and their implications in terms of potential origins of MSTIDs, are also discussed.

**Figure 8.** SRMTID index (in TECUs), in terms of GPS time (x-axis) and local time (y-axis), for the four selected networks: (top left) AS, (top right) CA, (bottom left) HW, and (bottom right) NZ.

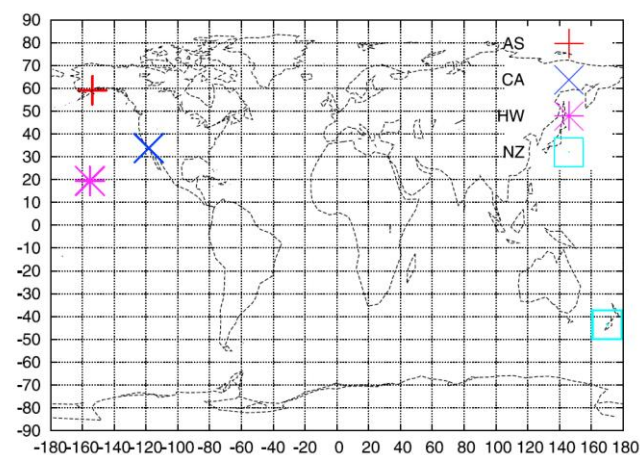

MSTID @ AS: days [81,173], 2004-2011

MSTID @ CA: days [81,173], 2004-2011

MSTID @ HW: days [81,173], 2004-2011

MSTID @ NZ: days [265,356], 2004-2011

**Figure 2.** Global location of the local GPS networks analyzed in this work, at South of Alaska (AS), California (CA), Hawaii (HW) and New Zealand (NZ).

**Figure 16.** Polar plots representing MSTID velocities (in m/s) and azimuths, similar to Figure 14 but for local spring.

## Conclusions from d2VTEC300s?

- **Conclusion:** The double-difference in time of  $LI=L1-L2$ , with time steps of 300 seconds (a good indicator of the most frequent ionospheric waves, difficulting the “interpolability” of the ionospheric delay from permanent GPS networks to GPS users. MSTID signature) is more intense during the night time.
- **Question 12:** Is this result in agreement with the climatology study in local networks? Why?

# Recent works in MSTID: a simple RT mitigating approach for precise GPS processing

AGU PUBLICATIONS

Radio Science

RESEARCH ARTICLE

10.1002/2016RS006159

**Key Points:**

- Direct and simple MSTID mitigation technique (dGII) for GPS observations
- dGII is applicable to differential GPS processing (just one baseline is needed)
- Precise positioning is improved by means of dGII, in terms of ambiguity fixing and convergence time

**Abstract** In this paper, the authors summarize a simple and efficient approach developed to mitigate the problem in precise Global Navigation Satellite Systems (GNSS) positioning originated by the most frequent ionospheric wave signatures: the medium-scale traveling ionospheric disturbances (MSTIDs). The direct GNSS Ionospheric Interferometry technique (hereinafter dGII), presented in this paper, is applied for correcting MSTID effects on precise Real Time Kinematic (RTK) and tropospheric determination. It consists of the evolution of the former climatic Differential Delay Mitigation Model for MSTIDs (DMTID), for real-time conditions, using ionospheric data from a single permanent receiver only. The performance is demonstrated with networks of GNSS receivers in Poland, treated as users under real-time conditions, during two representative days in winter and summer seasons (days 353 and 168 of year 2013). In range domain, dGII typically reduces the ionospheric delay error up to 10–90% of the value when the MSTID mitigation model is not applied. The main dGII impact on precise positioning is that we can obtain reliable RTK position faster. In particular, the ambiguity success rate parameter increases, from 74% to 83%, with respect to the original uncorrected observations. The average of time to first fix is shortened from 30 s to 13 s. The improvement in troposphere estimation, due to any potential impact of the MSTID mitigation model, was most difficult to demonstrate.

## RESEARCH ARTICLE

10.1002/2017JA023988

### Key Points:

- We introduce a new method that estimates both the number of unknown traveling ionospheric disturbances and its parameters from GNSS data
- The method has been successfully assessed with simulated data (on real pierce point locations) and real data from GEONET in Japan
- This new approach can be applied to other regions with dense GNSS networks and can be extended to study seismic-related ionospheric waves

**Abstract** The medium-scale traveling ionospheric disturbances (MSTIDs) constitute the most frequent ionospheric wave signatures. We propose a method for detecting the number of simultaneous MSTIDs from a time series of high-pass-filtered Vertical Total Electron Content (VTEC) maps and their parameters. The method is tested on the VTEC map corresponding to a simulated realistic scenario and on actual data from dual-frequency Global Positioning System (GPS) measurements gathered by +1200 GPS receivers of the GPS Earth Observation Network (GEONET) in Japan. The contribution consists of the detection of the number of independent MSTIDs from a nonuniform sampling of the ionospheric pierce points. The problem is set as a sparse decomposition on elements of a dictionary of atoms that span a linear space of possible MSTIDs. These atoms consist of plane waves characterized by a wavelength, direction, and phase on a surface defined, the part of the ionosphere sounded by the GEONET (i.e., 25°N to 50°N of latitude and 125°E to 155°E of longitude). The technique is related to the atomic decomposition and least absolute shrinkage and selection operator. The geophysical contribution of this paper is showing (a) the detection of several simultaneous MSTIDs of different characteristics, with a continuous change in the velocity; (b) detection of circular MSTID waves compatible by time and center with a specific earthquake; (c) simultaneous superposition of two distinct MSTIDs, with almost the same azimuth; and (d) the presence at nighttime of MSTIDs with velocities in the range 400–600 m/s.

and A. Aragón-Àngel<sup>1,2</sup>

Received 6 June 2012; revised 14 October 2012; accepted 18 October 2012; published 12 December 2012.

[1] A new GNSS Solar Flare Activity Indicator (GSFLAI) is presented, given by the gradient of the ionospheric Vertical Total Electron Content (VTEC) rate, in terms of the solar-zenithal angle, measured from a global network of dual-frequency GPS receivers. It is highly correlated with the Extreme Ultraviolet (EUV) photons flux rate at the 26–34 nm spectral band, which is geo-effective in the ionization of the mono-atomic oxygen in the Earth's atmosphere. The results are supported by the comparison of GSFLAI with direct EUV observations provided by SEM instrument of SOHO spacecraft, for all the X-class solar flares occurring between 2001 and 2011 (more than 1000 direct comparisons at the 15 s SEM EUV sampling rate). The GSFLAI sensitivity enables detection of not only extreme X-class flares, but also of variations of one order of magnitude or even smaller (such as for M-class flares). Moreover, an optimal detection algorithm (SISTED), sharing the same physical fundamentals as GSFLAI, is also presented, providing 100% successful detection for all the X-class solar flares during 2000–2006 with registered location outside of the solar limb (i.e., detection of 94% of all of X-class solar-flares) and about 65% for M-class ones. As a final conclusion, GSFLAI is proposed as a new potential proxy of solar EUV photons flux rate for strong and mid solar flares, presenting high sensitivity with high temporal resolution (1 Hz, greater than previous solar EUV irradiance instruments), using existing ground GNSS facilities, and with the potential use as a solar flare detection parameter.

# Real-time GIMs

The availability of the IGS RT datastreams with latencies of less than few seconds, containing the multi-frequency, multi-constellation GNSS measurements of hundreds of worldwide permanent receivers, is being crucial to extend the computation of ionospheric models in real-time at continental or global scale.

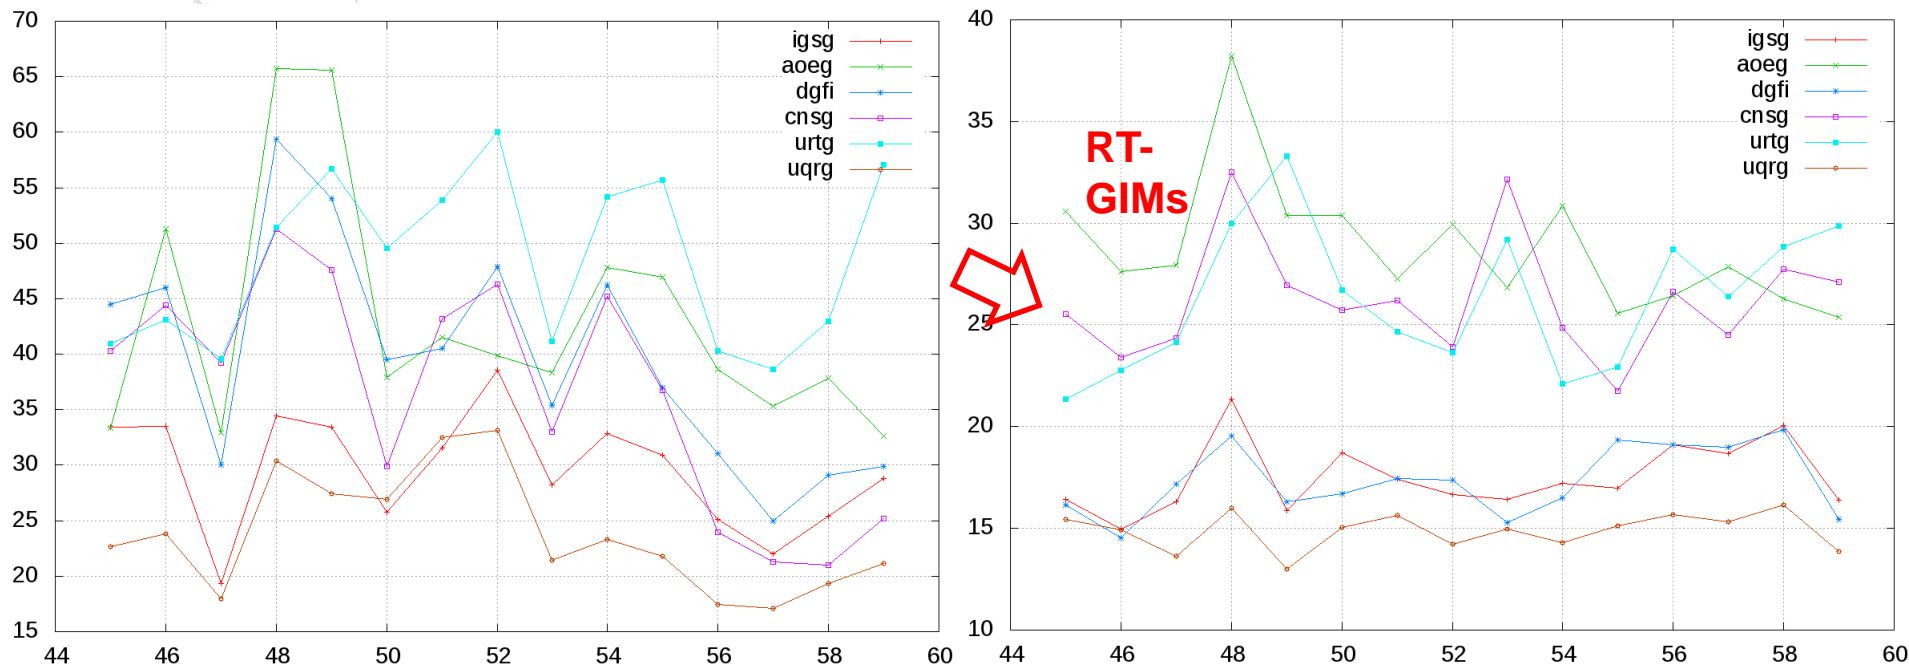

We are going to summarize some recent initiatives, comparison and results in this regard, since IGS2016 WS:

- 1) Recent comparison of some RT and NRT VTEC models (Roma-Dollase et al. 2016).
- 2) Questionnaire & Analysis centers already in position to contribute to a combined IGS RT-GIM soon (starting by the end of 2017, García-Rigo et al. 2017).
- 3) Thoughts on potential RT combination strategies.
- 4) Apparent limitation of present ionospheric RTCM message and simple solution.
- 5) Conclusions and recommendations.

# 1) Recent comparison of some RT and NRT VTEC models: *External validation vs VTEC-JASON2*

VTEC Relative RMS error (% , taken as reference VTEC-JASON2) vs day of year 2016: Left plot is only for the European region while right plot is worldwide (extracted from Roma-Dollase et al. 2016 @ BSS2016).

# 1) (Cont) External validation vs dSTEC-GPS @ independent receivers

GIM	RMS [TECU]	RMS max [TECU]	RMS min [TECU]	BIAS [TECU]
AOEG	11.8	22.6	4.8	-1.43
CNSG	9.2	18.8	3.0	0.21
URTG	8.2	14.9	3.4	0.30
DGFI	5.6	10.8	1.8	-0.57
IGSG	6.2	11.6	1.9	-1.01
UQRG	4.6	9.1	1.1	-0.61

RT-  
GIMs

35 GPS stations have been used. The dSTEC RMS has been calculated for the days of year 2016 from 45 to 59.

## 2) Questionnaire & Analysis centers to contribute to an IGS RT-GIM:

### *Questionnaire on Real Time (RT) and Near Real Time (NRT) Data Products performed in the RT-IM WG*

Global and regional ionosphere maps of different parameters, available with latencies ranging from 15 minutes down to 2 minutes.

- Vertical Total Electron Content (VTEC)
- F2 layer critical frequency (foF2)
- F2 layer maximum height (hmF2)
- W index
- F2 layer bottomside thickness (B0) and shape (B2)
- Rate of TEC Index (ROTI)

(Most usual, but they may be others we are not currently aware)

# 2 (Cont.) RT/NRT Data Products Distribution

Only two specific formats for ionosphere data:

- IONEX
- RTCM SSR

Other general purpose formats:

- HDF5
- Web page
- Image
- General Purpose text format: HDF5, CSV, JSON
- ASCII Text data with internal formats

Distribution itself is done through:

- HTTP or web service
- FTP

And only one method exclusive for GNSS/ionosphere data: Network Transport of RTCM over Internet Protocol (NTRIP)

## *2 (Cont.) Analysis centers which might contribute to a combined IGS RT-GIM soon*

**CNES** already transmits RT-GIM (RTCM iono. Messages from PRODUCTS.IGS-IP NTRIP caster)

**UPC-IonSAT** already transmits RT-GIM (IONEX format)

**WHU** already transmits RT-GIM (IONEX format)

**CAS** is very interested to transmit RT-GIM by the end 2017 for the RT IGS combination. Currently testing the stability of software, accuracy of RT-GIM, and trying to get more global real-time data streams (internal format, but it can be adapted).

**NRCAN** interested to join future RT-GIM IGS product. Currently, they produce near-real-time global vTEC maps (IONEX and spherical harmonic coefficients, no schedule yet for RTCM format). An offline comparison and comb. is suggested.

### 3) Thoughts on potential RT ionospheric combination strategies: *i) weighting*

RT Weighting scheme	PROS	CONS
[A] "Self-consistency" (reference: L1-L2 at the same elevation in the same phase continuous arc...)	The same which is being already applied for final and rapid combination with common mapping	We have to wait to the second (elevation-decreasing) half of each arc, i.e. half number of performance estimations...
[B] "dSTEC" (reference: L1-L2 at max. elev. ....)	Well characterized (e.g. recent paper); it only demands to store the reference LI, which is less affected by mapping errors	Same than [A] "Self-consistency"
[C] "RT-dSTEC" (The first L1-L2 measurement in the arc is taken as reference)	Full data availability, only one data stored per arc	The low elev. Ref. STEC is typically the (or one of the) very bad estimated ones, affecting all the time series.
[D] = [C] (during the ascending arc part) + [A] (during the descending part)	Full data availability, only one memory record per arc (updated at max. elevation).	Potential "overweight" of the first low-elevation reference ray (potentially mitigated with elev. mask).

# dSTEC-GPS layout

$$\begin{aligned}\Delta S_O &\equiv S_j^k(t) - S_j^k(t_{E \max}) \\ &\approx M \cdot V(t) - M_{E \max} \cdot V(t_{E \max})\end{aligned}$$

### 3) (Cont.) Other considerations in RT ionospheric weighting strategies

ii) Weighting directly the SH coefficients (taking into account the analysis centers contributing to such order degree) seems feasible (due to the corresponding orthogonality of the basis function on the complete ionosphere) and faster.

iii) Performance temporal prediction of weights: This can be an important aid for the weight estimation, in order to avoid any latency inconvenient. A potential low / variable degree polynomial might be used for this task among other possibilities.

## 4) Apparent limitation of present ionospheric RTCM message and simple solution: *RTCM VTEC*

- RTCM currently only defines one way to provide VTEC information to the users, as a spherical harmonic series to a given order and degree (message type 1264).
- At some point at least it was under discussion as far as we know to have a message type with data representing a grid, equivalent to the IONEX file content.
- In our knowledge, the maximum order and degree allowed by the standard is 16.
- We want to analyze which is the loss of precision for the end user by using spherical harmonics instead of directly the IONEX content.

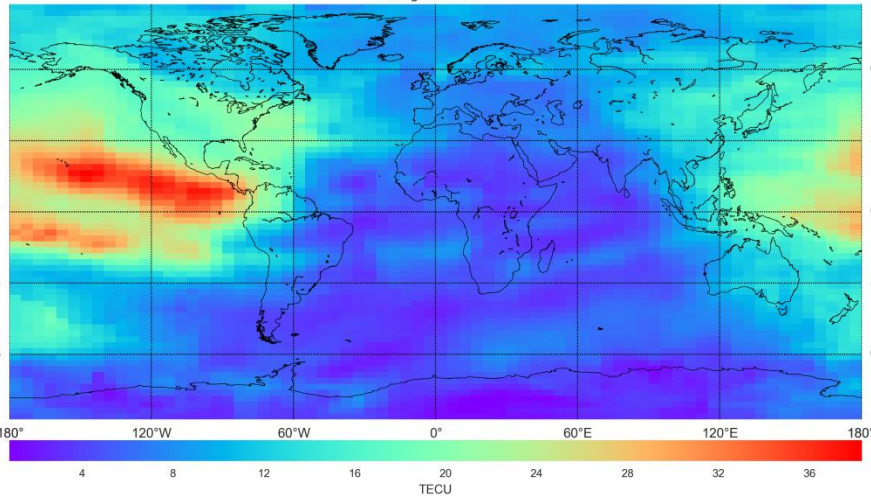

# 4.(Cont) Importance of using the right SH order/degree

ORIGINAL GIM

(UQRG1480.17i, 00UT)

Original VTEC

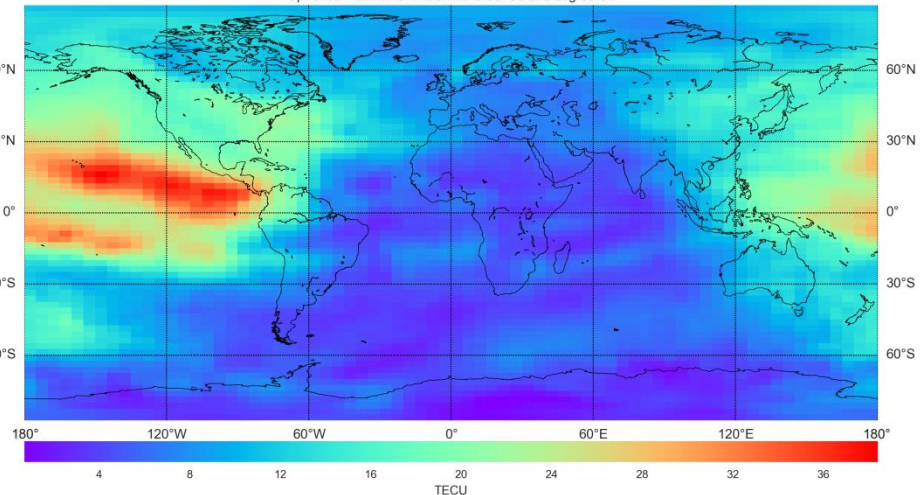

Spherical Harmonic VTEC with order 8 and degree 8

Spherical Harmonic VTEC with order 16 and degree 16

Spherical Harmonic VTEC with order 32 and degree 64

Reconstructed GIM **5.8% error**  
(deg=16 & ord=16, max. RTCM?)

Reconstructed GIM **1.8% error**  
(degree=64 & order=32)

# 4.(Cont) *Distribution of relative errors*

$$\text{RMS relative error } 100 * \sqrt{\sum (VTEC_{SphHarm} - VTEC)^2} / \sqrt{\sum VTEC^2}$$

# Conclusions / recomendation

- The availability of RT-IGS GNSS is already allowing the continuous monitoring of ionospheric electron content distribution (RT-GIMs), variability (ROTI) and Space Weather response (e.g. EUV flux rate during solar flares), among practical applications (precise farming).
- We have focused on new results which can facilitate the generation of a combined IGS RT-GIM soon:
  - 1) Recent comparison of some RT and NRT VTEC models.
  - 2) Analysis centers ready or interested to contribute to a combined IGS RT-GIM soon.
  - 3) Initial discussion of potential RT combination strategies.
- Apparent limitation (order & degree not larger than 16) of present ionospheric RTCM message and simple solution.
- Recommendation: to increase maximum supported RTCM SH order & degree

# Comments to Fig.11 of Hang et al. 2017

- This finding, obtained thanks to the extreme sensitivity of the new ADDTID technique, might be generated by two earthquakes of magnitude M4.6 and M4.9 in a 3 min interval (recorded at respectively 17:29 and 17:26 LT in U.S. Geological Survey (USGS) [2011a, 2011b]). These earthquakes occurred a few hundred seconds before the detected waves and are compatible with the center of the circular ionospheric wave. A similar precedent of a delay between occurrence of the 2011 Japan Tohoku earthquake and the circular wave disturbances detected over Japan is reported in Tsugawa et al. [2011]. In this case the delay was of about 7 min after the earthquake.
- The novelty of this finding, regarding previous works performed on major earthquakes (with magnitudes greater than 6), is the detection by the perturbation on the ionosphere despite the relative low magnitude of the earthquake.

## Scenario 2: Wide not dense GPS network. Case study of major Illapel earthquake on Chile, 2015

- Earthquake happened at Chile on Sep., 16th 2015, 22:54 UTC.
- Gathered from dual-frequency GPS observations taken on few dozens of Argentina & Chile permanent GPS receivers.
- The next results were mainly computed from double-time-difference of VTEC @ 300s (i.e.  $d2VTEC_{300s}$ , mainly focused on ionospheric periods from 400 to 1200s).

# Method 1: Time evolution of map of detrended VTEC values.

- The distribution of bandwidth filtered detrended VTEC values (d2V) was not providing a direct evidence of circular waves associated with the Chile earthquake of Sep., 16th 2015[\*], on the contrary than for the Tohoku earthquake of March, 11th 2011[\*\*].
- This might be related with a simultaneous coincidence of much lower density of permanent receivers in Chile/Argentina (compared with the +1200 GNSS rec. on GEONET network on Japan), and with a lower ionospheric effect, in between the signature of the southern peak of the equatorial anomaly

# Method 2: detrended VTEC on a epicenter distance vs. main shock time span 3D plot

- In such situation we have reduced one dimension from (lon,lat,time,d2V) to (dtime,distance,d2V) where “dtime” is the time elapsed since the earthquake mainshock and “distance” is the distance of the ionospheric pierce point to the earthquake mainshock epicenter, following the procedure of Lognonne et al. 2006.

Reference: Lognonné, P., Artru, J., Garcia, R., Crespon, F., Ducic, V., Jeansou, E., ... & Godet, P. E. (2006). Ground-based GPS imaging of ionospheric post-seismic signal. *Planetary and Space Science*, 54(5), 528-540.

Chile\_EQs: focus on -71.654 -31.570 15 259 82473 (Detrended VTEC / TECUs @300sec)

## (A) Co-seismic circular wave signature with similar parameters than in previous EQs

One and half cycle of circular waves clearly seen starting at ~23:03, about 8 minutes after the Illapel EQ main shock (22:54:33 UTC = 22:54:50 GPStime = 82490 sec), showing a range of velocities of 1000 km in 0.3 hours = 0.93 km/s to 1000 km in 0.55 hours = 0.51 km/s) and wavelength from ~100 km close to the epicenter to ~200 km at 1000 km.

Such distribution is very similar to the distribution observed at Hokkaido EQ. by Lognonné et al. (~600 s. after main shock and with velocities in between 0.74-1.5 km/s with wavelength ~500 km).

# Detr. VTEC vs. EQ distance and time: Whole EQ day (259, 2015)

# Conclusions

- The real-time ionospheric sounding with GNSS is playing an increasing role in improving different areas, such as precise real-time positioning, space weather monitoring, earthquake signatures and potential tsunami detection, among others.
- Many of the above mentioned contributions can be easily implemented in real-time.

***MANY THANKS FOR YOUR ATTENTION!***
